Figure 2: Scope execution policy

Package manager installation (Chocolatey)

Chocolatey is a package manager for Windows (like apt-get or dnf, but for Windows). It was designed to be a decentralised framework for quickly installing applications and tools that you need. It is built on the NuGet infrastructure, and currently uses PowerShell to deliver packages from the distros to your computer.

Note: Inspect all scripts downloaded from the Internet prior to running them on your local system. All of these scripts download a remote PowerShell script and execute it on your machine.

```
$ (New-Object System.Net.WebClient).DownloadString('https://chocolatey.org/install.ps1')
```

After we inspect the script, we can install Chocolatey using the following command:

```
$ iwr https://chocolatey.org/install.ps1 -UseBasicParsing | iex
```

The cmdlet `iwr` allows us to extract data from the Web. This will pass the script to the `iex`.

The cmdlet `iex` will execute the contents of the script, running the installation script for the Chocolatey package manager.

Installing Python

To install Python, use the following command:

```
$ choco install -y python
```

After the installation is finished, you can check the version of Python installed on your machine by using the following command:

```
$ python --version
```

The output should be something like what's shown below:

```
$ python v3.5.1.20161002
```

Along with Python, `pip` is also installed. To upgrade it to the latest version, run the following command.

```
$ python -m pip install --upgrade pip
```

Setting up the environment

One can keep the dependencies required by different projects in separate places, by creating virtual Python environments for them. This solves the 'Project X depends on version 1.x but Project Y needs 4.x' dilemma, and keeps your global site-packages directory clean and manageable.

You can set up as many programming environments as you want. Each environment is basically a directory or folder in your computer that has a few scripts in it to make it act as an environment.

To create a new directory named `myproject`, use the following code:

```
$ mkdir myproject
$ cd myproject
```

Once you have entered the directory, you can create an environment, as follows:

```
$ python -m venv myenv
```

To use this environment, you can activate it by using the following command:

```
$ myenv\Scripts\activate
```

We can now install Django.

Installing Django

Use the following command to install Django:

```
$ pip install django
```

Once this is completed, use any editor to create Django apps. The most preferred one is `PyCharm`. You can download it from <https://www.jetbrains.com/pycharm>.

I hope that helps!
