

Eight Top-of-the-Line Open Source Game Development Tools

The open source game development tools presented in this article give developers numerous options to explore and choose from, as per their requirements.

Open source game development is generally looked upon as a tech enthusiast's hobby. Rapid advancements in technology, combined with the various innovations being launched every day, have put tech experts and gamers in a win-win situation. Open source provides interoperability, high quality and good security in game development. Little wonder then that open source platforms are already being used for quite a few successful and complex games.

The following points highlight some of the advantages of the open source gaming platforms.

- **Better quality and more customised software:** With the source code being available on open source gaming platforms, professional developers can customise features and add varied plugins as per their own requirements, which is beneficial for game development companies.
- **Say good bye to licensing:** With completely open source platforms, there is no requirement for any sort of licensing. So apart from no licence costs, other issues like tracking and monitoring are also avoided.
- **Lower cost of hardware:** Open source gaming platforms in Linux involve lower hardware costs compared to Windows. With the advantages of easy portability and high compression, Linux requires low hardware configurations. So, game development costs are lower and even legacy hardware systems can be used for game development.

Let's take a look at the top open source gaming development platforms, which give developers numerous options to explore and choose from, as per their requirements.

GDevelop

GDevelop is an open source, cross-platform game creator platform designed for novices. There is no requirement for any sort of programming skills. GDevelop is a great platform to develop all sorts of 2D and 3D games. It consists of several editors on which games can be created. The list is as follows.

- **Project manager:** This displays the open games in the editor, allowing developers to set and organise the scenes. Users can select the scene to be edited and modify the parameters like the title, background colour, text, etc. It also gives access to the image bank editor of the games, and allows the user to select the extensions to be utilised by the game.
 - **Image bank editor:** This allows the user to manage all sorts of images via objects. It supports transparency integrated in the image.
 - **Scene editor:** This allows users to organise the scene at the start, positioning the object in the scene.
 - **Object editor:** This allows the creation of objects to be displayed on the stage, like text and 3D box objects. It also has the 'Particle Transmitter' object, which allows developers to use particles in the game with ease.
 - **Layer editor:** This allows users to manage the interface that remains motionless, while allowing the camera of the rest of the game to move or zoom.
 - **Event editor:** This allows users to animate the scene, depending on the conditions and actions that will be performed on the objects of the scene.
- The events are compiled by GDevelop in machine code — the mechanism is simple and similar to writing C++ code.
