

components contain malware or vulnerabilities. According to the report, the average application development project has 49 vulnerabilities spread across 80 direct dependencies.

However, these difficulties are frequently exacerbated by the presence of indirect dependencies. According to the report, these transitive dependencies contained 40 per cent of all vulnerabilities. Worryingly, only 18 per cent of respondents said they are confident in the transitive dependencies controls they have in place, and only a quarter are concerned about the security impact of their direct dependencies.

According to the report, open source teams are struggling to meet an increasing demand to find and patch these bugs -- the time required to fix open source vulnerabilities is nearly 20 per cent longer than in proprietary projects. It increased in length from 49 days in 2018 to 110 days last year. This could be due to a lack of personnel. According to 30 per cent of organisations that do not have an open source security policy, no one in their teams is currently addressing open source security directly.

Snyk's director of developer relations, Matt Jarvis, commented on the report: "Software developers today have their own supply chains — instead of assembling car parts, they are assembling code by patching together existing open source components with their unique code. While this leads to increased productivity and innovation, it has also created significant security concerns. This first-of-its-kind report found widespread evidence suggesting industry naivete about the state of open source security today."

Planetarium Labs receives 32 million dollars in Series A funding

Planetarium Labs, a community-driven gaming company, has got US\$ 32 million in Series A funding from Animoca Brands, Samsung Next, and WeMade. The funds will be used to create a blockchain based gaming ecosystem, in which players can participate in the game network while also giving community members a seat at the table.

The company announced that it is developing a gaming environment based on Libplanet blockchain technology, which will allow gamers to join the game network

while also giving users a voice in open source content development. Planetarium Labs will expand basic tools for community-driven gaming and player governance, as well as enable key studios to deliver sophisticated Web3 gaming experiences. To encourage participation, the company intends to focus on the Libplanet ecosystem for decentralised gaming and establish a variety of projects such as an ecosystem fund and community assistance programmes.

Meta develops AI based translation tool for 200 languages

Meta has developed a single artificial intelligence based model capable of translating 200 different languages, including many that are not currently supported by commercial tools.

The company, according to *The Verge*, is open sourcing the project in the hope that others will build on its work. The AI model is part of Meta's ambitious R&D project to develop a "universal speech translator," which the company sees as critical for growth across its many platforms, from Facebook and Instagram to developing domains like VR and AR.

Machine translation not only allows Meta to better understand its users (and thus improve the advertising systems that generate 97 per cent of its revenue), but it could also serve as the foundation for a game-changing app for future projects such as its augmented reality glasses.

Experts in machine translation told *The Verge* that Meta's latest research was ambitious and thorough, but that the quality of some of the model's translations would likely be significantly lower than that of better-supported languages such as Italian or German. Angela Fan, a META AI research scientist who worked on the project, stated that the team was inspired by the lack of attention given to such low-resource languages in this field.
