

Key features of the cloud platforms used for machine learning

- Algorithms or features extraction
- Association rule mining
- Big Data based predictive analytics
- Classification, regression and clustering
- Data loading and transformation
- Data preparation, data preprocessing and visualisation
- Dimensionality reduction
- Distributed linear algebra
- Hypothesis tests and kernel methods
- Processing of image, audio, signal and vision data sets
- Model selection and optimisation module
- Preprocessing and dataflow programming
- Recommender systems
- Support for text mining and image mining through plugins
- Visualisation and plotting

application that identifies the speaker's or writer's feelings and opinions. Sentiment analysers can quickly decipher what someone is thinking and feeling in a piece of writing, such as an email or a review. Sentiment analysis can be used to assess a review-based portal, in decision-making applications, etc.

There is a lot of interest in employing machine learning algorithms in the healthcare industry. Emergency room wait times can be predicted across multiple hospital departments by using an ML algorithm. Details of staff shifts, patient data, and recordings of department discussions and emergency room layouts are all used to help create the algorithm. Machine learning algorithms can be used for detecting a disease, planning treatments, and prognostication.

Cloud based deployment of AI and ML applications

The applications of AI and ML can be deployed on cloud platforms. A number of cloud service providers nowadays enable programmers to build models for effective decision-making in their domain.
