

Why Enterprises Should Opt for Platform as a Service

Platform as a Service enables quick and easy creation of Web applications without the necessity of buying and maintaining the software and infrastructure underneath it. This article explains why it's useful.

Platform as a Service (PaaS) refers to cloud computing services that provide a platform for customers to develop, run and manage applications without the complexity of building and maintaining the infrastructure associated with developing and launching them. This is the core platform on which cloud native applications and supporting systems are based.

PaaS typically involves diverse application software infrastructure capabilities including application platforms, integration platforms, business analytics platforms, event-streaming services and mobile back-end services. In addition, it includes a set of monitoring, management, deployment and related capabilities.

Developers are keen on getting their environments up without waiting, while operations teams care about

performance and stability. This often gives rise to some conflict between them. PaaS creates a peaceful environment for both groups. An application platform delivered as a service is described as PaaS, and is used to deploy the user code. Cloud Foundry, Cloudify and OpenShift open source environments can be used as PaaS.

PaaS adoption pattern

Cloud computing must satisfy five
