

How Companies can Benefit from Amazon's Cloud Native AI and ML Services

Amazon makes extensive use of artificial intelligence services. These services are aimed at delivering personalised recommendations to end users, such as forecasting the number of customers planning to buy a new product. Read on for a detailed introduction to AWS cloud native AI and ML services.

and configurable computer vision capabilities.

AWS Panorama: Allows operation of self-contained computer vision applications at the edge.

Amazon Comprehend: Easily extends and understands useful information from a document's text.

Amazon Textract: Extracts printed text, handwriting and data from any document automatically using machine learning.

Amazon Translate: Neural machine translation service for quick, high quality language translation.

Amazon Polly: Converts text into a lifelike voice, allowing the creation of apps and speech enabled devices.

Amazon Transcribe: Converts speech to text automatically.

Specialised services: These are customised and tailored for a specific mission.

The need for AI-integrated businesses is growing by the day, but the skills required to construct services from the ground up are in short supply. AWS offers comprehensive AI/ML capabilities that may be readily integrated into any application, even if you don't have a skilled team. Instead of developing an AI service to meet business needs, using AWS's pretrained services would be more time-efficient. Let's take a quick look at some of these services.

Cloud native architecture is a design methodology that makes use of cloud computing services like EC2, S3, Lambda from AWS (Amazon Web Services), etc, to facilitate dynamic and agile application development techniques. These services take a modular approach to building, running and updating software via a suite of cloud based microservices as against a monolithic application infrastructure.

The support for microservices and containerisation gives agility and dynamic capability to cloud native applications so that it becomes easy to transfer these between cloud providers and services deployment in varied

languages, without any conflicts or migration issues.

Amazon AI services can be used to produce AI solutions in the shortest possible time. These services are divided into two categories:

- Core
- Specialised

Core services: These are further divided into four categories — vision, text, chatbot and speech.

Amazon Lex: Uses the same technology as Alexa for speech recognition and language understanding.

Amazon Rekognition: Extracts information and insights from images and videos using pretrained
