

How to Create a Kubernetes Cluster Using Google Kubernetes Engine

The Google Cloud Platform (GCP) offers a managed Kubernetes service that makes it easy for users to run Kubernetes clusters in the cloud without having to set up, provision, or maintain the control plane. This article takes a quick look at running a Kubernetes cluster in GCP, using Google Kubernetes Engine, and then deploying a Node.js application on it.

In a production environment, when the user load increases or decreases, there is a need to scale up or scale down the resources. To facilitate a container's resource management services, Google developed the Kubernetes container orchestration technology. The process of automatic deployment and management of running containers followed in Kubernetes is known as container orchestration. There are multiple container orchestration solutions available today including Docker Swarm, which is specific to Docker containers, and Mesos from Apache.

Docker Swarm is easy to set up but lacks some of the advanced auto scaling features. Mesos, on the other hand, is quite difficult to set up. Kubernetes is one of the top ranked choices for
