

“Ant is willing to share our resources and innovations with other industry players and explore the value of privacy computing technologies together,” said Tao Wei, vice president and the chief information security officer at Ant Group.

As the world becomes more digital, the demand for privacy-preserving computation grows. According to Gartner, by 2025, 60 per cent of large organisations will use at least one privacy-enhancing computation technique in analytics, business intelligence, and/or cloud computing.

OpenReplay raises US\$ 4.7 million in funding

OpenReplay, an open source session replay tool for developers, has raised US\$ 4.7 million in new funding to grow its community, accelerate deployment at scale, and improve user experience. The seed round was led by Runa Capital, with participation from Expa, 468 Capital, Rheingau Founders, and Tekion co-founders. According to PitchBook, OpenReplay has raised US\$ 6.2 million to date, including the new funding.

OpenReplay, which was founded in 2018, provides an open source session replay suite that assists developers in reproducing issues in their Web apps. Session replay software enables a company to record and visually replay a session in order to better understand a user's experience. The solution from OpenReplay combines session replay with powerful DevTools, allowing developers to see where users are getting stuck and troubleshoot issues more quickly by making debugging visual.

The company claims that bugs are unavoidable and that fixing them begins with reproducing them, which is a time-consuming process in production environments. Websites become more difficult to replicate as they grow in complexity to full-fledged applications. Developers can use OpenReplay's DevTools to examine logs, diagnose errors, track performance metrics, inspect HTTP payloads, and record the entire application's state.

The tool combines session replay, DevTools, and performance monitoring to allow developers to easily replay everything their users do on their Web app and understand where and why they became stuck. Using live session replay and co-browsing capabilities, OpenReplay's service can also be used to assist customers directly on the website while they are browsing — no more cryptic reports, screenshots, and endless back-and-forth emails with customers. Data never leaves a company's infrastructure because OpenReplay is self-hosted.

Only 3 per cent of open source software bugs are attackable: AppSec report

With vulnerability-management workloads increasing in an era of increased software supply chain security risks, a new study suggests that only about 3 per cent of today's flaws are actually reachable by attackers. According to the data, if application security (appsec) professionals and developers work together to fix and mitigate what is truly attackable, they can drastically reduce the strain on their teams.

The 2022 AppSec Progress Report from ShiftLeft suggests that appsec and development teams can more effectively sift through vulnerabilities by focusing on the “attackable” ones. According to the report's findings, developers saw a 97 per cent reduction in false-positive library upgrade tickets after taking attackability into account when examining packages in use with critically rated vulnerabilities.

Analysing for attackability also entails determining whether the CVE-containing package is loaded by the application or is in use by it, whether the package is in an attacker-controlled path, and whether it is reachable via data flows. In essence, it means approaching open source vulnerabilities with a simplified threat modelling approach, with the goal of drastically reducing fire drills.

These drills are already all too familiar to CISOs. When a new high-profile supply chain vulnerability, such as Log4Shell or Spring4Shell, hits the industry back channels and then makes headlines, their teams are called to work long days and nights determining how these flaws affect their application portfolios, and even longer hours applying fixes and mitigations to minimise risk exposures.
