want to monitor the data. You can drill down the information for a particular user, query or time that you may select, as can be seen in Figure 1.

The blue area can be seen as selected, and you can get the information from that particular area about the people that are connected, the queries used, etc. You can simply drill into these queries and fetch the relevant details in MySQL.

A secure database

All databases need to comply with various regulations such as HIPPA: Privacy of Health Data, Sarbanes Oxley: Accuracy of Financial Data, and EU Data Protection Directive: Protection of Personal Data. MySQL enables all these certifications easily.

Databases are prime targets for hackers because there are so many people who are accessing them. Applications, the operating system, on-going backups, and networks are often highly susceptible to hacking.

MySQL is secure by default. It secures each channel which interacts with the database. This includes all the internal logging, message passing and all the information that is uploaded and exchanged on the cloud.
