

Figure 7: Compatible applications for MySQL

Figure 8: MySQL Autopilot

Now, if users want to carry out analytics, they can use the Heatwave in-memory database on the Oracle Cloud. This is a single database, where all the queries go to MySQL. Based on the nature of your queries (OLAP or OLTP) MySQL decides if the data is suitable to reside inside it or in HeatWave. There is no need to do an ETL, and all the clean-up is done automatically. You can do OLAP queries in real-time, as can be seen in Figure 5.

After the data is inserted, it gets stored in the memory wherever it is represented. Once it is placed there, you can do an analytic query. The data that is being queried is the latest data and not an old version that you have ETL'ed.

Whether you have an OLTP (online transaction processing) or

OLAP (online analytical processing) application, everyone can access it with MySQL. If you have any analytics platform such as Tableau, Qlik, or Looker, then you can just connect it with MySQL services and it will work seamlessly. You can then access it from anywhere you want to.

Why should you migrate from Amazon RDS or Aurora?

You might be wondering why you should be considering pulling out

from Amazon RDS or Aurora to a MySQL database service. There are a couple of reasons for this. HeatWave has an 18 times lower latency rate compared to Aurora. It has a much higher throughput and is at least 60 per cent cheaper than Aurora. HeatWave is also 18 times faster than Redshift AQUA, and has almost seven times higher performance than the Snowflake database. All of these benchmark tests are available on GitHub for you to access. You can download and run them on your own as well. All you have to do is search for 'HeatWave benchmark tests'.

Understanding MySQL Autopilot

When you are on the cloud and try to understand what people are really doing, you will see that oftentimes they are making a lot of mistakes. MySQL Autopilot addresses this issue. For instance, while doing some provisioning, users may fail to optimise it as certain nodes and parameters could be changed in a better way. The amount of parallel connection that might be required while loading a lot of data can also be optimised. If there is an error due to memory expiration or you run out of memory, this can be taken care of as well. In general, your cloud service provider can use MySQL Autopilot to understand exactly what you are doing and give you advice if something goes wrong (Figure 8).

MySQL has proven its worth time and time again. Many industrial analysts are considering using our OLAP as well, since it is fairly recent in the market. **END** 🐧
