

Fleet unveils open source, cross-platform mobile device management solution

Fleet has announced the release of a new programmable MDM (mobile device management) solution that is intended to give medium- to large-sized businesses control over the security of distant workstations with unmatched GitOps and workflow automation. Because Fleet is an open source MDM solution, it is not only more affordable for businesses looking to cut costs, but also gives users the freedom to customise the platform to suit their needs without incurring extra costs or delays.

Fleet can be easily set up to share data across teams and is seamlessly linked with third-party platforms and DevOps processes via a REST API. It offers out-of-the-box support for macOS, Windows, Linux, and ChromeOS. This makes it simple for IT engineers and administrators to access data, conduct queries, and modify the application development and delivery procedures. Additionally, it offers two-way transparency, enabling organisations to build and sustain employee confidence while preserving data security by letting end users see what is being watched.

IT teams can manage devices with Fleet's user-friendly dashboard's one-click visibility and management from any place or platform. It allows for remote locks and wipes, all of the CIS critical security controls for Mac and Windows, automatic enrolment of new employees with Okta or any identity provider, IT management of software updates and patching with any software manager (Puppet, Munki, Chef, etc), and disc encryption (for macOS using Apple FileVault). Additionally, Fleet enables numerous user accounts and thorough activity audits, allowing teams to seamlessly exchange data across departments without worrying about security or privacy issues.

MongoDB is no longer considered to be open source, according to FerretDB, as it is now distributed under the Server Side Public Licence (SSPL). SSPL is not appropriate for many open source and early-stage commercial projects, according to FerretDB. The company cites a blog post from Open Source Initiative to support this claim.

Drivers and utilities for MongoDB work with FerretDB. Along with RPM and DEB packages, Docker images are available for both development and production use.

Scythe Robotics unveils CAN based platform for autonomous lawn mower

The first open source project from Scythe Robotics, CANfetti, aims to simplify the process of adding new parts to autonomous lawn mowers. CANfetti uses the controller area network (CAN) bus based communication protocol CANOpen. The "backbone" of Scythe Robotics' autonomous mower, the M.52, is a CAN bus made for the automotive industry. The business said that other open source CAN frameworks were "too restricting" and that this led them to build CANfetti.

The company had trouble getting pre-existing CANopen stacks to function properly with the M.52. By using CANfetti, it was able to "integrate these and other crucial components into M.52, yielding significantly improved machine performance." Scythe has unveiled a number of new features intended to simplify development. The use of dynamic Object Dictionary types "ranging from std::string to an index assignable callback" is one of them. This enables "complete control over the reading and writing of an entry at the byte level," according to the company.

"Given the complex communication needs across the range of specialised components in Scythe M.52, we knew we'd have to leverage a higher-level CAN protocol," said Matt Quick, lead firmware engineer at Scythe, in a statement. "A number of our vendors already support CANopen, making it a great fit for us. But as advantageous as CANopen is, the available open source libraries were frankly a headache to integrate and had severe functional limitations, so we built our own solution."
