

Integration of Network Function Virtualization with the DevOps Pipeline:

Software Defined Networks

The fifth part of this series on integration of network function virtualization with the DevOps pipeline discusses the integration of network functions such as routing, switching, and forwarding in a software defined network (SDN).

We can no longer fulfill the network requirements of complex applications using traditional proprietary networking hardware. Hardware solutions cannot simply stand toe-to-toe with the growing demands of applications and their functionalities. Operators today require solutions that are scalable, flexible, and can fulfill the challenges

of mammoth network traffic. If only this could be resolved via virtualization of the various network functions. Well, that's what we'll discuss here, including how software defined networking can push for networking models with basic devices underneath it, which are easily scalable and not too costly.

Traditional networks have always been about hardware such as switches,
