

Secure your Enterprise with a Blockchain Defined Perimeter

In a traditional enterprise, all users, devices and systems are located and ring-fenced within a well-defined DMZ perimeter. Here, VPNs are leveraged to provide limited employees, clients and vendors with secure remote access to internal IT systems. Post the pandemic, however, almost all employees in many enterprises are working from home.

To quickly facilitate remote access to IT systems, many IT departments have started using VPNs for all. This may help in business continuity, but increases the security threat surface. This is where a blockchain defined perimeter comes in.

The hybrid work model is the new normal and traditional VPNs have become increasingly insufficient to address the needs of the modern digital enterprise. Cybersecurity is a critical concern for IT teams with so many people working remotely on their devices. VPN technologies lack the ability to enforce granular access control and network privileges. This is where zero trust and blockchain technologies are being leveraged for new solutions.

Blurred enterprise security perimeter

Vendors and clients now require anytime, anywhere, and instant access

to applications. The migration of IT infrastructure and systems to the cloud, the widespread use of bring your own device or BYOD, and IoT are the norm today. So the previously closed IT environment has quickly transformed into a hybrid, highly networked and widely distributed ecosystem. This growing 'mobility' of users and a swelling enterprise perimeter has resulted in greater exposure to cyberattacks. With the IT no longer centred on an enterprise's offices and internal data centres, the enterprise security perimeter is blurring. So security teams need to look at new approaches and technologies to secure the modern digital enterprise

ecosystem. The internet has become the enterprise network, and on-premises solutions can't establish secure network connections, especially with the advent of BYOD leaving the door open for hackers and unauthorised users. As a result, in today's hybrid world, a traditional hardware-defined network perimeter and trust model is no longer viable.

Software defined perimeter

A software defined perimeter (SDP) is a security methodology that distributes access to internal applications based on a user's identity, with trust that adapts based on context. First conceptualised by the US Defense Information Systems Agency
