

Choose the Blockchain for Your Enterprise Carefully

There is a growing belief that the adoption of blockchain will effectively break the monopoly over data that a few global enterprises concentrated in Silicon Valley have, and that Web 3.0 will play a critical role in end user participation and decentralisation of data. The fundamental premise of blockchain is that there is no central authority — it's governed by a network of users who establish the rules of participation,

The blockchain is being adopted rapidly across industries, which is a testament to the reliability of its underlying decentralised architecture. Today, blockchain use cases are common in supply chains, financial services, and healthcare, and are developing fast in many other domains. But a few challenges remain, and the choice of blockchain is critical.

which evolve according to consensus. Lack of central control allows for a decision-making mechanism in which a large group of people participate.

The World Wide Web was developed as a decentralised platform. It evolved into Web 2.0, which helped a few individuals tap into data and grow into global enterprises at breathtaking speed. Web 3.0, which is the next evolution of the World Wide Web, is expected to decentralise the control of data. In fact, the backbone of digital currency is the blockchain and its decentralised architecture. Bitcoin and Ethereum are popular cryptocurrencies today.

Current social and business structures have long been hierarchical in nature. The top-down command and control paradigm needs to evolve into a less centralised consensus mechanism. This involves a fundamental shift of how everything operates today; so it's going to be a while before effective models evolve into platforms for mass adoption.
