

working in collaboration. These choose to make some parts public and some private, including the ability to make a specific transaction public by using smart contract-based governance.

There is a lot more that goes into understanding each of the blockchain types along with their characteristics. An organisation interested in using a blockchain would have to review its requirements and answer a series of questions that help navigate the web of possibilities across all the four types of blockchains. Only then can it decide as to which type is better suited for its needs. Irrespective of the model an organisation chooses, there will always be compromises that would have to be made. How efficiently a blockchain is managed without impacting the overall security, scalability, and reliability of the system depends on its design and implementation. Typically, it's difficult to change the type of blockchain once

a path is chosen; so it is important to ensure all the characteristics are well understood before embarking on the enterprise blockchain journey.

At the end of the day, blockchain is an asset that will help enterprises increase their reach with customers. By building streaming and time series integrated analytics for the blockchain, organisations can address the challenges of stale data on legacy systems with fresh intelligence in real-time, creating

an everlasting impression on customers.

What is evident is that a decentralised, user-driven, social consensus way of developing technology has arrived. What remains to be seen is governments adopting it for social causes and enterprises for end user transparency. There is little doubt that blockchain is a revolutionary technology that's destined to have a disruptive impact on the way technology is applied in everyday life. **END**
