

2x more wins than the leading competitor. This impressive performance in the EPFL competition is largely credited to Rapid Silicon's 'ABC-DE' algorithm, which is still pending patent protection.

Rapid Silicon is the sole FPGA vendor to compete in the EPFL benchmarking competition, breaching the long-standing tight control that FPGA firms have exercised over their EDA tools. As the first and only commercial open source FPGA design suite in the market, it is at the forefront of the programmable revolution, according to the company.

The EPFL Combinatorial Benchmark Suite is an open competition that was introduced in 2015. It is used to define new comparative standards for the logic optimization and synthesis community. In order to guarantee fairness, the EPFL releases a collection of unoptimized digital designs that are used to compare tools. The EPFL team then verifies the results. Located in Switzerland, EPFL is one of Europe's most prestigious science and technology universities.

Yandex open sources Userver, a framework for building highly loaded C++ apps

One of the biggest internet firms in Europe, Yandex, has made the Userver framework's source code and documentation available, making it simple and effective to develop highly loaded C++ apps. Userver is a technology that the corporation uses in a variety of services, including taxis, ultra-rapid grocery delivery, e-commerce platforms, and FinTech initiatives. The Apache 2.0 open licence governs the distribution of the framework.

for the creation of independent components (microservices) and their use in other apps as a result of Userver.

Microservices are autonomous, making it simple to update and add new features to an application built on such architecture. Thus, a similar job, like designating a courier to complete Yandex Delivery orders, can be carried out by using the

The development of applications that use a microservice architecture is best suited for Userver. The framework was initially created in the Yandex Taxi division. The team was able to go from a monolithic program to an architecture that allows

HomeGrid Forum unveils VectorBoost

The release of VectorBoost, an open source program for the GiGAWire profile that controls crosstalk prevention in broadband access networks, has been announced by the HomeGrid Forum. By utilising the GiGAWire profile, the initiative will hasten the development of network solutions based on ITU-T G.hn standards extended to the multi dwelling units (MDUs) environment, which includes large apartment complexes and office buildings, as well as single family units (SFUs) and fiber extender scenarios. In order to accommodate numerous users using bundled wires, it has crosstalk mitigation and auto pairing features.

The G.hn access feature known as VectorBoost enables a twisted pair copper telephone cable to operate at its highest efficiency even in the presence of crosstalk from other subscribers in the same binder. It can run locally on a GAM (G.hn access multiplexer) or in the cloud, and can guarantee the best resource distribution amongst adjacent lines in accordance with their real-time traffic requirements. As more computer resources become available in the carrier private cloud, VectorBoost can be readily enhanced and tailored to the needs of service providers.

By boosting the spectrum only when customers demand more bandwidth, VectorBoost optimises its allocation in addition to reducing crosstalk between pairs of a copper binder. When used in conjunction with coordinated dynamic time allocation (cDTA), it provides the ideal bandwidth distribution for each G.hn link in real-time.

The VectorBoost compute engine interacts with each of the VectorBoost drivers that are running in the GAM as part of the GAM firmware or in a cloud server.
