

According to CERT NZ, it funded the Catalyst team's efforts to enhance the Heimdal snapshot. Since Samba 4.0, a snapshot of the Heimdal Kerberos implementation has been incorporated. The update includes crucial new security features like FAST, or Kerberos request armouring. Using a wrapper created with a stronger password, this tunnels ticket requests and answers that may be encrypted with a weak password. Additionally, work has been done to enhance the plugin interface.

The new upgrade makes Samba more compatible with Windows 2012 and makes it simpler to update the system.

CIX Technology is now a member of the Windows on Arm Group

The Windows on Arm Group of Linaro Ltd, an open source collaborative engineering organisation creating applications for the Arm environment, has welcomed CIX Technology Inc. (CIX Technology) as a member. The goal of the Windows on Arm Group is to create a robust, self-reliant Arm open source ecosystem for Windows. The group is enabling engineers to create natively for Windows on Arm and recompile more quickly by providing support for a wide variety of tools, languages, and frameworks. Up to this point, successes have included the introduction of Qt 6.2 with Windows on Arm hardware as a technology preview, and the availability of the Windows 10 on Arm bot support and binary as part of the LLVM 12.0.0 release.

The mission of CIX Technology is to advance intelligent computing for Arm based client devices. By investigating tools for Arm native development and advertising them in the local market, the company is joining the group to aid in the advancement of the worldwide Windows on Arm ecosystem. Additionally, the business intends to collaborate with Linaro on creating a boot architecture implementation that complies with Arm SystemReady, which is essential for OEM/ODM clients that want to design personal computing client devices using the Arm architecture.

"We're seeing big momentum with regards to Arm architecture adoption in the PC market segment, and our goal is to design Arm-compatible intelligent computing solutions for Windows devices," said Gang Liu, co-founder & software engineering VP at CIX Technology. "In order to achieve this we need a strong Arm open source ecosystem which supports application migration and native development on Windows. Linaro is the best place for us to contribute with other industry leaders in a coordinated way and we are thrilled to be joining."

OpenChrome DRM/KMS driver not yet ready for integration into Linux 5.20

Around one month ago, the sole developer left working on open source VIA x86 graphics support for Linux intended to mainline this 'OpenChrome' DRM/KMS driver for the Linux 5.20 cycle. Even though Linux 5.19 is published and the Linux 5.20 merge window is now open, the OpenChrome DRM driver is still in the development stage.

For the Linux 5.20 merge window, the OpenChrome DRM/KMS driver has not yet been queued into the DRM-Next tree. According to the most recent activity, at least one more patch series revision is still required to resolve outstanding problems identified during the current 'v3' round of review. Before the code is integrated, the outstanding issues must be resolved.

Since they rarely pose a threat to present customers, new drivers are occasionally submitted after the merge window has closed. There is still a potential that something similar will occur, but it is more likely that the OpenChrome driver will be delayed by at least one more cycle.

This OpenChrome DRM/KMS driver has been in development for more than ten years, albeit intermittently, and is intended to work with the VIA CLE266/KM400/K8M800/P4M800 Pro/PM800/P4M890/K8M890/P4M900/CX700/VX800/VX855/VX900 chipsets. Kevin Brace was the last developer actively involved in advancing open source VIA x86 graphics driver support. However, even as of 2022, this OpenChrome driver does not yet provide 2D or 3D hardware acceleration; therefore it is essentially adequate for kernel mode-setting and display functions.

The driver will only be loaded by default if the 'via.modetest=1' kernel option is passed and will be treated as "experimental" when it is finally integrated, at least until 2D acceleration is implemented.
