Data analysis has become imperative for companies, and there is a huge demand for data-driven applications with user friendly interfaces. This article tells you how to develop an interactive web app using the Shiny package in R, which is a popular programming language for data science.

Nearly every business across the world relies on data today, in some way or the other. In fact, data science has helped transform many businesses by using data-driven applications, whether in the field of finance, banking, retail, logistics, e-commerce, transportation, airlines, or any other.

High performance computers and low-cost storage allow us to predict results in minutes today rather than the many hours it used to take earlier. Data scientists focused on the future are developing easy to use applications with high performance and multi-dimensional visualisation. It all starts with Big Data, which consists of three components: quantity, diversity, and velocity. Algorithms and models are fed from this data. The most cutting-edge data scientists working in machine learning and AI are creating models that self-

improve, detecting and learning from their errors.

Statistics and computing are used to turn data into useful information in the field of data science, often termed as data-driven science. Data science is a synthesis of methods from a variety of fields to gather, analyse, and interpret data in order to develop new insights and make choices. The technological disciplines that constitute data science include statistics, probability, mathematics, machine learning, business intelligence, and some programming.

Data science can be applied in various areas (Figure 1). The analysis of large, complicated data sets is the focus of data science. It has helped to create a new universe in which data is seen in whole new ways. Tech giants like Amazon, Google, and Facebook use data science principles for business intelligence and decision making.
