

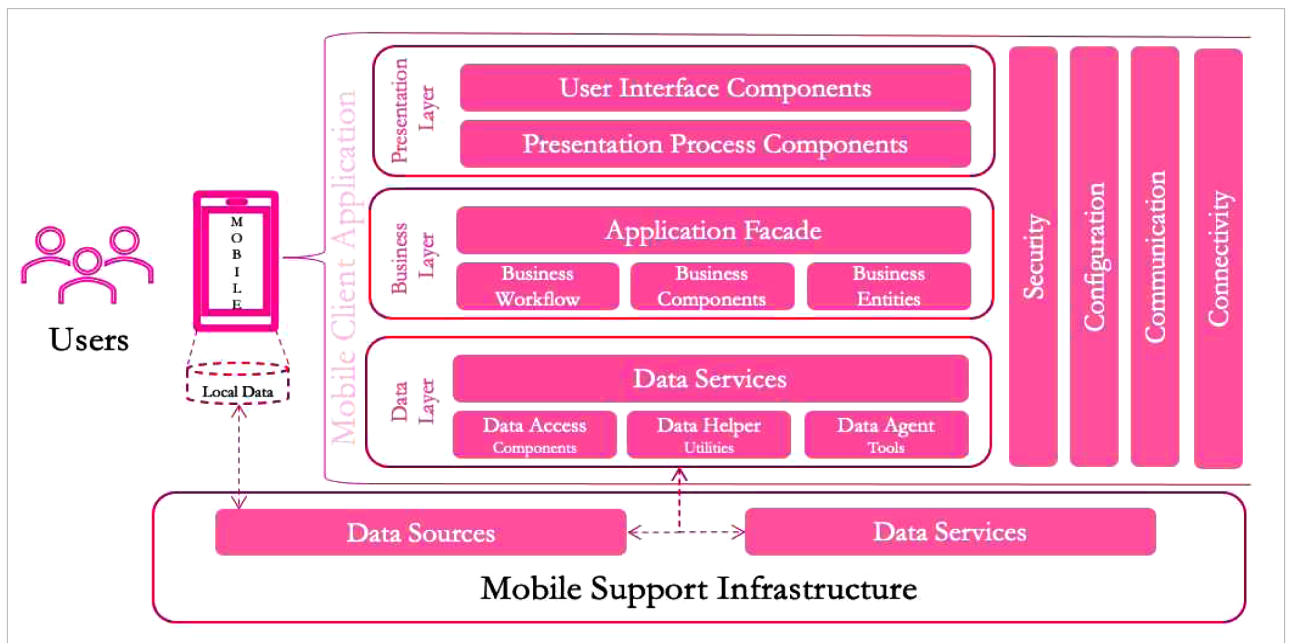

Figure 1: Mobile app reference architecture

development, depending upon its priorities and business needs

Enterprise mobile app reference architecture

Finally, it is important to understand the ecosystem in which the mobile app must be developed and deployed. Careful consideration of the mobile application's presentation layer, business layer and data layer components, overall application security, configuration, communication, and connectivity expectations will ensure a modularised mobile app that can be easily maintained and evolves with the ever changing world of technology. Applying industry best practices to identify critical use cases with their business requirements, data and governance, identity and personalisation, design, management, and endpoint connectivity will help create a reference architecture. This architecture will act like a central focal point bringing all stakeholders together under one mission — successful development of a mobile application that meets an organisation's business needs.

Mobile data analytics

Better business insights are generated with the help of real-time analytics of historical and streaming data. The data platform is used as a single source of truth that users across the organisation have access to. Such an objective requires planning right from the design phase of the mobile application, removing redundant tasks for frontline customer support, thus enabling a smart app that responds to customers.

At the end of the day, a mobile app is an enterprise asset that will help increase its reach with customers. While building streaming and time series integrated analytics for the mobile application, organisations can address the legacy systems challenges of stale data with fresh intelligence in real-time. Detailed planning in the development process will help build long-lasting trust with prospects and customers alike. **END** 🐧
