

Use Microservices for Developing IT Service Products

Microservices are especially suitable for IT service product development. Let's take a quick look at the microservice architecture, its benefits, and the open source tools available for it.

IT service challenges

Microservices evolved as a solution to overcome monolithic applications. As IT services are different from regular applications, microservices are a natural fit for IT service product development.

IT applications are complex. They are integral to many isolated services. For successful system operations, administrators interact with many services and unite them. Communication between services is important and forms the IT utility. The microservices architecture approach is a modern way of developing IT applications unifying many isolated services, each running in its own process and communicating with lightweight mechanisms, often as an HTTP resource API. The goal is to create synergy, reduce development

complexity of integrated solutions, ease deployment headaches, reinforce resiliency, and increase release velocity.

A few benefits of microservices in the context of IT service development are listed below:

- Microservices support asynchronous invocation, which is essential for integrated IT services.
- They enable headless architecture by wrapping the business logic and functionalities in a set of APIs, which are powered by specialised IT services at the backend. Frontend channels can hook into these APIs.
- Microservices decouple systems of engagement (SoE) with systems of record (SOR) through well-defined API contracts.

'Microservices' is an architectural style through which we can build applications in the form of small autonomous services. This architecture enables decoupling of different services. APIs are procedures and functions that allow consumers to use the underlying service of an application. Microservice architecture helps in mobile and web application development, and is suitable for IT service product development too.
