

recognition can help achieve Identity Assertion Level 2 (IAL2), which, according to NIST, is the strongest form of identity attestation that can be done by a machine. (IAL3 entails having a human verify the identity of the user.) The identity of the user is noted so that in case of any issues, he or she can be tracked down in the real world.

A single sign on (SSO) service that asks the user to complete authentication and identity assertion activities on a smartphone application is the suggested implementation. The answer to that question is passed on to the 'service provider' application, where the login request is made. An appropriate software development kit (SDK) and/or application programming interface must be made available by the SSO (APIs). The majority of Metaverse engines, remote devices, IoT devices, virtual reality headsets, and native and console apps support this. SDKs are used for the same.

The user must request to be authenticated to a certain 'service provider' as part of the authentication process in the system. The request is forwarded by the service provider to the server hosting the system. The server sends the same request to the smartphone application and includes information about the 'service provider' in the message. The user can then opt to continue with the authentication procedure after verifying the information on the app.

This article covers the advantages of using MetaKey for identity management and Metaverse authentication. The suggested approach is helpful in preventing identity thefts that take advantage of authentication mechanisms. Additionally, it can help reduce cyberstalking, harassment, and other associated problems in the Metaverse. The large variety of accessible SDKs makes it easy to implement MetaKey on any Metaverse engine, which can safeguard users' assets and identities online. **END** 🐧
