

Indian HPC Users Get Access to Customised & Cost-effective Solutions

Bangalore-based IT solutions company, **Digital Waves**, promises to give Indian researchers, academic institutions and large organisations powerful new solutions in high performance computing after its recent alliance with Russian supercomputing company, T-Platforms. This article takes a peek into their plans.

Talk about Indian test cricket and every cricket fan will swear by the Sachin Tendulkar-Rahul Dravid duo that has the maximum number of century partnerships to its credit. The recent partnership between Digital Waves, a Bangalore-based IT solutions company, and T-Platforms, a Russian supercomputing firm, is one that holds the promise of similar results in India's high performance computing (HPC) arena. Progressing from the heavy-on-the-pocket supercomputers of yesteryears to its cost-effective Power-X HPC clusters, Digital Waves has once again overcome issues of migration, speed and performance with its recent alliance.

"The partnership will offer one of the world's best blade server designs and HPC solutions to Indian research and defence organisations. The Indian market can avail new powerful solutions for high-performance computing for all verticals like strategic/scientific computational research, oil and gas exploration, CFD (computational fluid dynamics), bio-medical/bio-informatics, weather modelling/prediction, etc," says V. Ranganaath, head of Enterprise Solutions

at Digital Waves. Mikhail Kozhevnikov, vice-president, T-Platforms, adds, "Our partnership with Digital Waves is a great step forward in introducing Russian supercomputer technologies to foreign markets. We have already made ourselves known in the CIS (Commonwealth of Independent States, which comprise former provinces of the USSR), have started getting active in Europe and Africa, and now we are entering the Asian market."

HPC today

But before analysing what Digital Waves offers in high performance computing, a quick overview of this domain is essential.

High performance computing is used to solve problems that require significant computational power, or problems that need to access and process large quantities of data, very quickly. It involves developing parallel processing algorithms and software, that is, programs that can be divided into little pieces so that each piece can be executed simultaneously by separate processors.

Traditionally, universities, research organisations and companies used supercomputers for number crunching in
