

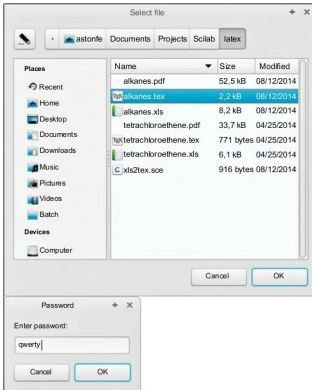

Figure 3: Two examples of Zenity dialogue boxes

```
7za a -mem=AES256 -pPASSWORD -tzip archive.zip file1.txt file2.txt
```

To unzip, use `7za e archive.zip` (the 'e' option stands for 'extract'), and to clear the terminal history, simply use `history -cw`.

Zenity is free software and a cross-platform program that allows the execution of GTK+ dialogue boxes in the command line and shell scripts (see References 3 and 4), and in Mint, it's installed by default. The following bash script can be used to zip (with encryption) one file or one directory:

```
#!/bin/bash
# File archive with AES encryption
# F=$(zenity --file-selection --directory --title='Select directory')
F=$(zenity --file-selection --title='Select file')
P=$(zenity --entry --title='Password' --text='Enter password:')
7za a -mem=AES256 -pSP -tzip $F.zip $F
```

An example is shown in Figure 3 — one dialogue box is about the file selection and the other for entering the encryption password. The following script is to unzip an archive:

```
#!/bin/bash
# File extract
F=$(zenity --file-selection --title='Select file')
```

```
P=$(zenity --entry --title='Password' --text='Enter password:')
7za e -pSP $F
```

I'm used to using only 7-Zip to zip, because the simplest way to unzip an archive is to use the default archive manager and also because, in the case of an encrypted archive, a prompt for the password is shown.

Efax

The first thing to know is which port your modem is available on. In this example, an external USB modem is considered. From the terminal window, type `lsusb` and look if the modem is recognised. It's probably recognised on the `ttyACM0` port. Sometimes it may not be so easy and further tests may be needed. According to Reference 5, some privilege changes are required:

```
sudo chmod +s /usr/bin/fax
sudo chmod +s /usr/bin/efax
sudo chmod +s /usr/bin/efix
```

Then edit the configuration file with `sudo gedit` (or `gvim`) `/etc/efax.rc` and change some options as follows:

```
DEV=ttyACM0
FROM="[your-faxnumber]"
NAME="[your-name]"
PAGE=a4
```

In the following example for the terminal window, a file called `filename.ps` is sent to the number 0123456789:

```
fax send -v 0123456789 filename.ps
```

With Zenity, the previous operation can be done with the following bash script:

```
#!/bin/bash
# Fax send
F=$(zenity --file-selection --title='Select file')
N=$(zenity --entry --title='Fax number' --text='Enter the fax number:')
fax send -v $N $F
```

I use Efax only to send a fax, so I haven't tested it to receive one. More sophisticated faxing solutions are achieved with the Hylafax fax server and with the YajHFC client (Yet another Java HylaFAX client) as reported on <http://www.yajhfc.de>, but some testing is required mainly for the configuration of Hylafax.

Another example of Zenity's usage is password generation. In Mint, the APG (automated password generator) utility is installed by default, and can be
