

Enterprise Linux and OpenShift via certified containers, but is supported by Red Hat and extended via the integrated hybrid support partnership between Microsoft and Red Hat,” the Red Hat team members wrote in a statement.

The new development is aimed to help enterprises build new solutions on .NET and test them directly on computing platforms other than Windows. This might be considered as a backdrop for Microsoft’s own operating system. However, the software giant is targeting to please more developers through the new announcement.

Microsoft claims that about 18,000 developers from over 1,300 companies have already contributed to the initial development of .NET Core. This is just the beginning, but certainly quite a huge one to make the new platform successful in the market.

Microsoft could use developer contributions in expanding its existing product offerings. Also, the extensive community support would bring .NET in line with Java and other developer platforms.

Developers can leverage solutions like Portable Class Libraries (PCL) to take advantage of .NET Core 1.0 and enhance their existing apps. Likewise, there are Xamarin tools to enable app development for multiple platforms using the new open source model.

Microsoft isn’t alone in the race to develop new open source technologies. Facebook and Google are working with the community. While Facebook has framework React to support developers, Google is making things easier for the AI world through TensorFlow.

The verdict on how successful .NET Core is has not come out. Nonetheless, it already has brought Microsoft closer to Red Hat and the ever-growing open source community.

Microsoft releases WebRTC version of Skype for Linux

Months after its much anticipated arrival, Microsoft has finally released a new version of Skype for Linux client. However, the app isn’t as advanced as the one for Windows or Mac systems, and is backed by the open WebRTC project.

The new Skype for Linux is an alpha version. This explicitly confirms the presence of some bugs and an inferior user experience over its counterparts on other platforms such as Windows, Mac and Android, among others.

“As you may have guessed by the name, Skype for Linux Alpha is not a fully functioning Skype client as of yet. We’re sharing it with you now as we want to get it in your hands as soon as possible, so we can continue to develop the new version together. Once you’ve downloaded the app, you’ll notice that

Fedora 24 now out with new Linux experience across the cloud, desktop and server

Red Hat’s community-driven open source operating system has been updated to Fedora 24. The new version brings an all-new Linux experience across the three distinct editions — Fedora 24 Cloud, Fedora 24 Server and Fedora 24 Workstation.

In its beta version, Fedora 24 comes preloaded with Glibc 2.23 (the latest GNU C Library model) to deliver better performance than its predecessor. The developer community can also utilise some improvements to POSIX compliance and GNU Compiler Collection (GCC) 6. Moreover, the Linux 4.5.7 kernel is there to offer overall stability on each of the different Fedora editions.

“Fedora 24 continues Fedora’s drive to provide the latest, powerful open source tools and components to a variety of end users, from developers to systems administrators,” Fedora Project leader Matthew Miller said.

Fedora 24 Cloud comes with OpenShift Origin. The Kubernetes-based distribution enables a smoother experience for building and launching containerised applications. There is also Fedora Atomic Host to let developers run Docker applications and start their developments directly from Cockpit.

Red Hat’s Fedora Project already has over a million users on its open source operating system. This user base could reach new heights with the release of Fedora 24. It also sets the ground for a new version of Red Hat Enterprise Linux (RHEL) and certainly takes Linux to new levels.
