

Figure 1: The Greasemonkey and Stylish add-ons for Firefox make it easy to manage and apply user scripts and styles

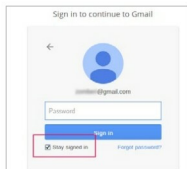

Figure 2: The 'Stay signed-in' checkbox in many big websites is selected by default. This means that these websites will continue to track you even when you click the 'Log out' link and when you are on any of their 'partner' websites. A 'partner website' is pretty much any website these days—anything that has its ads, social networking plugins or webmaster tools/tracker JavaScript

a Chrome clone and the Presto-engine-based Opera 12.x has become obsolete.

The utility of user scripts and user styles is best illustrated by examples.

User script examples

Figure 2 shows the well-known Gmail login page. There was a time when webmail providers would leave the 'Stay signed in' unchecked, by default. Now, it is checked by default (not just by Google but by other providers too). Unchecking this box every time you want to log in is an extra step that is easy to forget.

How do you get it automatically unchecked? This Greasemonkey script can do it for you.

Figure 3: This screenshot shows the text editor of the Greasemonkey add-on with the code to uncheck the 'Stay signed-in' checkbox

```
// ==UserScript==
// @name      Uncheck Google Signed-In Checkbox
// @description Automatically unchecks the "Stay signed-in"
//            checkbox
// @include    https://accounts.google.com/*
// @version    1
// @grant      none
// ==/UserScript==

document.addEventListener("DOMContentLoaded",
                           uncheckGoogleStaySignedInButton,
                           false);

function uncheckGoogleStaySignedInButton() {
    try {
        document.getElementById("PersistentCookie").checked =
        false;
    } catch (err) {
        console.error("UGSIC Greasemonkey Error: " + err);
    }
}
```

The Greasemonkey add-on executes this script on all pages matching the @include filter. The script finds the checkbox and unchecks it. With minor changes, you can make the same script work on the Yahoo Mail login page too.

Before writing the script, you have to find the HTML element ID of the checkbox. As any web developer worth his / her salt knows, this can be accomplished by right-clicking the checkbox on the Web page and selecting 'Inspect element' from the context menu.

Next, do you find the pre-roll Yahoo Mail page asking you for your phone number annoying? Then, this user script will automatically get you past the page.

```
// ==UserScript==
// @name      Bypass Phone Number Prompt on Yahoo Mail
```
