

click the 'trash' icon on every app page.

8. You can add a repository of your choice in F-Droid; for example, you can add the 'Guardian Project' repository (which hosts a number of apps for your privacy and security) along with the F-Droid repositories.
9. F-Droid alerts users about all the non-free components or any sort of tracking of user activity in the app.
10. The most recent version of F-Droid allows you to share apps with others nearby using the 'Swap Apps' option.

I have listed some apps that could be useful in your daily life and replace some of the closed source apps you're currently using on your phone.

SicMu Player

This is a simple audio player. It lists the music files in your device as one big play list, and these files are listed along with the current locations in a folder structure. All you have to do is click on the name of the folder in which you have kept your music file and choose your favourite song to play. It has only four control icons on the app.

1. Pause/Play
2. Forward and backward
3. Scroll to the current song
4. Disable the lock screen

Aside from these basic controls, you can have options like folding or unfolding your folder structure, shaking your device to play the next song, sorting your music files and saving the song's position.

There's no exit button on this app, but you can click the 'recent apps' button (i.e. the rectangular button in Motorola phones; other phones may have different buttons) on your device and close the app. It will show the message '*SicMu Player is Destroyed*' which assures you that the app isn't running in the background without your knowledge.

Pedometer

This app measures your steps and shows the calories you burned instantly. Though this app may seem simple, it has adequate features for your daily walking/running routine. It shows the number of steps and miles you've walked, the steps per minute, speed (in mph) and the calories you've burned.

It also has other options in its settings, so that you can have more control over the app, like the sensitivity of the detector, voice assistance on your progress and much more.

Wallabag

Wallabag is a mobile client for Framabag, which is an online service that could help you to store the Web pages from websites for offline reading.

To use Wallabag, you first need to create an account with Framabag, and once that is done, you're all set to start saving your Web pages. If you're working on your personal machine, then please download the official Wallabag

extension for the Chrome/Firefox browser.

Download Wallabag from F-Droid, and the main window of the app presents you with three options:

1. List of articles and how many of them are unread
2. Synchronise
3. Settings

'Settings' requires your Framabag URL, your user ID and your token. Once you've provided these, you can synchronise the app so that whatever you have saved in the Framabag account will be imported to Wallabag.

You can create an e-book by converting your articles to EPUB, MOBI and PDF format.

Telegram

There are many instant messengers available for Android, but only a few of them are secure and guard your privacy during online chat sessions.

Telegram is one of the best choices when you are considering an open source chat application with strong security against all possible attacks. Telegram focuses on speed and security. Unlike the prominent messaging app WhatsApp, this one has many cool features for its users, such as:

1. Secret chats
2. Self-destructing messages
3. Support for almost every known file type
4. Groups can have 200 members and can upgrade to super groups with a membership count of 1,000 members
5. There are many channels as well as bots available for telegrams, which can be added to your telegram app

You can increase the security of the app by setting up a pass code, which is required when you are launching the app.

SMSSecure

As the number of Internet users grows each year, very few still resort to the traditional messaging method, SMS. There are many apps which ensure that your online chats are secure from third parties. But what about SMSs? Textsecure was the only viable option for securing your SMSs but as of March 2015, they have withdrawn their support for SMS. Hence, SMSSecure was born.

SMSSecure is purely focused on SMS. This app fully replaces your stock SMS messaging. To use this app, you are not required to register with any service. It works like a normal SMS.

It is important that both sender and receiver use SMSSecure to achieve encrypted SMS communication; if not, you can still send a normal SMS to your receiver.

Despite being a fork of Textsecure, SMSSecure adds various enhancements to the codebase, such as:

1. All messages are encrypted locally, so even if your phone is lost, your messages are still safe.
2. The screen security enables you to block screenshots inside the app.
