

on a particular cloud platform. In its current form, however, the platforms have matured to a great extent, and have taken this dependence away. The applications can be built once using technology that users are comfortable with, and optionally, they can choose to either deploy them to their own data centres or to a cloud platform of their choice.

12. It is not 'All or nothing'

Enterprises have invested considerably over the years in data centres that host their 'Line of Business' applications. It would not be viable for them to discard all the investments and move their workloads overnight to the cloud. Enterprises, however, could choose those workloads that have outgrown their deployment capacity in the data centre, or where there is a greater business advantage in moving an application to the cloud rather than retaining it within their data centre. They could also consider building and deploying their newer applications in the cloud as composite applications that, in addition to using data residing in the cloud, would also pull in data from on-premise Line of Business applications. This way, enterprises could retain their existing investments, and at the same time leverage the power of the cloud for the larger benefits it provides to their business.

Another reason why not all applications move to the cloud is due to data sovereignty restrictions that prohibit data being stored in a public cloud outside the country. There is flexibility, however, to have processed and obfuscated data moved to the cloud.

The public cloud provides numerous options to securely connect to on-premise applications. There are different ways in which a hybrid scenario could be implemented, depending on the needs of an enterprise. A few examples are highlighted below.

- Existing 'Line of Business' applications in an enterprise were probably implemented a decade back, and built for use from the confines of the corporate intranet. Enabling them for BYOD based access from the public Internet would imply numerous internal teams to come together to implement changes across one or more applications to make this possible, each probably on a different set of technologies and platforms. Such an initiative would probably be a non-starter given these challenges. Using the hybrid cloud approach, an enterprise can enable secure communication for this scenario in a non-intrusive way.
- Where existing Line of Business applications do not have a DR strategy implemented for their current set of applications, the cloud would provide an effective DR infrastructure, with the necessary tools and technologies to orchestrate the backup and recovery of on-premise infrastructure to the cloud or to an alternative on-premise data centre through the cloud.
- When some Line of Business applications cannot be moved to the cloud for various reasons, ongoing
