## Your first android application

So far, you know what App Inventor is and how to run it on your computer. Now, I'll tell you how to make your very first Android application and, once again, I am saying it is pretty simple. You will not require any programming or coding knowledge for this.

Login to your App Inventor

account using the steps mentioned above and you will land on the **My Projects** page.

1. Since you have not developed any projects so far, it will not display any list under **My Projects**. We will begin our first project, by clicking on the **Start New Project** button.
2. Let's give a suitable name to the

project. Since it is our first project together, let's call it *First\_Project*. Please keep in mind that if your project name has more than one word, then you should use the underscore (\_) character to join them as App Inventor doesn't allow using spaces. Click on the **OK** button to proceed.

3. You will now see something similar to the image shown in Figure 8. This is the main page for the development. Here, we will add various components to our project and then add the respective functionality. Don't worry, I will brief you about the various things you will see on the page. The page you are currently viewing is called the *designer* because we design the app here.

Although we have named our application/project '*First\_Project*', nothing has been said about what it is supposed to do. We must always have a clear idea of what the app will do, so let's list that out.

## Objective

We want to make an app that will work as a theft alarm. The phone will make the sound of a siren whenever it is moved.

So let's think about what the app should look like.

## GUI requirements

For now, there is no special GUI requirement, but rather than keeping the screen blank, it is better to show an image on the phone screen that signifies 'danger'. We need to upload an image and a sound that we want to play.

We will require the following components for this project.

## Steps to be taken to create the application

1. Drag and drop the button onto the viewer.
2. Now select the **Sound** under **Media** and drop it into the viewer. You will see it placed under non-visible components.
3. Now, from the **Sensor** category, choose **Accelerometer Sensor** and
