

Add the following code before the `</body>` tag:

```
<script id="new-contact.html" type="text/ng-template">
<div class="modal">
  <!-- Modal header bar -->
  <ion-header-bar class="bar-secondary">
    <h1 class="title">New Contact</h1>
  </ion-header-bar>

  <!-- Modal content area -->
  <ion-content>
    <form ng-submit="createContact(contact)">
      <div class="list">
        <label class="item item-input">
          <input type="text" placeholder="Enter name of
Contact" ng-model="contact.title">
        </label>
      </div>
      <div class="padding">
        <button type="submit" class="button button-block
button-positive">Create Contact</button>
      </div>
    </form>
  </ion-content>
</div>
</script>
```

We are again using AngularJS here. We have created a template for input in a script tag, which will be controlled by the controller. To add a controller, open `app.js` and add the

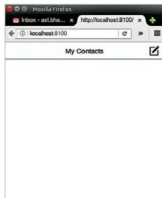

Figure 8: `myContact` new output in browser

following line before the `.run` line in the file:

```
// Create and load the Modal
$ionicModal.fromTemplateUrl('new-contact.html',
function(modal) {
  $scope.contactModal = modal;
}, {
  scope: $scope,
  animation: 'slide-in-up'
});

// Called when the form is submitted
$scope.createContact = function(contact) {
  $scope.contacts.push({
    title: contact.title
  });
  $scope.contactModal.hide();
  contact.title = "";
};

// New contact modal
$scope.newContact = function() {
  $scope.contactModal.show();
};

// Close the new contact modal
$scope.closeNewContact = function() {
  $scope.contactModal.hide();
};
});
```

Try to look at the methods, which are self-explanatory. When we click on a new button on the header, a `new-contact.html` will be displayed with a form. Type the contact name in this form and click on the Create Contact button. This will close the `new-contact.html` form and will update the contact list on the main UI screen.

To test the application in the browser, run the `ionic serve` command in a terminal, which will open the browser as shown in Figure 8.
