

DC/OS works, who's involved and how the project will grow," the Mesosphere team has written in a blog post.

While Microsoft will offer its Azure Container Service through the DC/OS, Canonical is in the process of leveraging its Juju to enable a full-fledged open source solution for data centres. The project is based on Apache Mesos technology that was originally developed as a distributed systems kernel back in 2009.

"DC/OS is the only open source project that bundles all these functions together into a single software distribution," Microsoft's Azure architect John Gossman said in a statement.

Microsoft and HP are the two investors in San Francisco-based Mesosphere that was co-founded by Tobi Knap, Florian Leibert and Benjamin Hindman in 2013. Originally, the team had designed Mesos as an open source platform, which will now take the shape of DC/OS.

The partners that are supporting the initial development of the Mesosphere DC/OS will get early access to its code as well as be able to integrate their proprietary technologies to extend and expand the new platform. However, the open source operating system itself will be available to other companies as well.

Basho brings out open source Riak TS database for IoT

Basho Riak TS version 1.3 is touted to be the "...only enterprise-grade NoSQL database" that has been optimised for IoT technologies. For an enhanced experience, it comes in an open source form whereby developers can not just download the software for free but can also tweak its code and develop new applications with time-series data.

"I'm really excited about what we've been able to deliver in Riak TS 1.3. However, this is just the beginning," Dave McCrory, CTO, Basho, wrote in a blog post. "The time-series market is quite broad, and there are more than a few very interesting needs in the time-series market that we are looking to address. In addition to being a fantastic general purpose time-series solution, we have specifically chosen to focus on IoT, which has a number of requirements that fall outside of what a general time series database provides," McCrory added in his post.

Seattle-based Basho released the first version of its Riak TS in October last year. Although the initial release was aimed at the proprietary market, its new version is designed as an open source solution that brings a time-series data

solution for IoT. The new database additionally expands support for SQL commands and comes with API support as well as a multi-cluster replication.

A time-series data solution is vital for the IoT as it marks data with a timestamp for sources such as sensors. "A very common goal is implementing tools built for operational efficiency. Especially as data variety grows — in the form of unstructured, often time-stamped IoT data — deriving value from data more quickly and at lower costs will be paramount for competitive advantage," said Nik Rouda, senior analyst, ESG, in a statement.

Riak TS is not exclusive to customers opting for open source. It is also available to commercial customers who want to perform the associated queries and transactions on time-series data at the time of maintaining high availability and scale.

Based on Riak Core, the new Riak TS version is claimed to have a 'masterless architecture' that offers operational simplicity and high availability. There is also Apache Spark integration that has integral support for Spark Streaming, DataFrames and Spark SQL.

You can install Riak TS version 1.3 directly on your data centre or on a public cloud infrastructure. Alternatively, AWS Amazon Machine Images (AMI) will also be available for the time-series data solution to let you experience its presence from your AWS Workplace.
