

TESTING WEB APPS WITH SELENIUM

Selenium is an open source tool for testing Web apps. It was initially created by ThoughtWorks and now boasts of a dynamic group of designers and clients.

The project development stages of any Web application always end with the testing phase. Testing can be of two types — manual and automated.

Manual testing: This is the oldest method of finding errors in your software. The main goal of manual testing is to ensure that the application is error-free and is working in accordance with the functional requirements of the system. The most common example of manual testing is Black Box and White Box testing.

Automated testing: Software test automation uses special tools to control the execution of test cases, and compares the actual results with the expected results. Usually, regression tests are the ones that are automated. Automated testing is used in cases where there is repetition of code and where requirements do not change frequently.

How testing is automated

We can automate our testing process with the help of a simple scripting language and any automated software application. The various steps to achieve automated

testing are mentioned below:

1. Recognising the areas in your code that need to be tested. If that code is repeated very often, then you sure do need automated testing.
2. Choosing the correct tool for automated testing.
3. Writing proper scripts that will cover large portions of your software.
4. Developing test suites to make sure that the automated test cases run one after the other.
5. Executing the scripts.
6. Building result reports.
7. Recognising the problems and trying to resolve them.

Popular tools that are used for functional automation

Product	Vendor
Quick Test Professional	HP
Rational Robot	IBM
Coded UI	Microsoft
Selenium	Open source software
Auto IT	Open source software
