

Build, Deploy and Manage Custom Apps with IBM Bluemix

IBM's Bluemix affords developers an opportunity to build, deploy and manage custom apps. Bluemix is built on Cloud Foundry. It supports a number of programming languages as well as OpenWhisk, which allows developers to call any function without the need for resource management.

Bluemix is an open standards, cloud-based platform implemented by IBM. It has an open architecture which enables organisations to create, develop and manage their applications on the cloud. It is based on Cloud Foundry and hence can be considered as a Platform as a Service (PaaS). With Bluemix, developers need not worry about cloud configurations, but can concentrate on their applications. Cloud configurations will be done automatically by Bluemix.

Bluemix also provides a dashboard, with which developers can create, manage and view services and applications, while monitoring resource usage also.

It supports the following
