

“Docker IS A **BOON TO** DEVELOPERS”

Containers are becoming vital for the development of software applications. While several container technologies are available in the market today to ease the software development process, Docker is leading the popularity race. In an interview with **Jagmeet Singh** of **OSFY**, **Docker captain, Neependra Khare**, highlights the advantages of using containerised application. He also mentions India's role in the growth of the Docker community. A few edited excerpts...

Q How does Docker make open source software development easy?

With container technology, we confine the application with all its dependencies such that it can run independently on different environments—be it the desktop, virtual machines or the cloud. We just need to have the container runtime like Docker installed on the host system.

Containers have been around for quite some time, but Docker and its tools made them more popular. Docker started a revolution and others joined in as well, which resulted in a very vibrant ecosystem around it. Now containers are becoming a basic unit of development and deployment. The same image from which we run a container is shared at different stages of the software life cycle. Because everyone from a developer to an operations engineer works on top of the same image, we don't get complaints such as, “It doesn't work in my environment.”

Docker has a concept of the registry, which is similar to GitHub. This feature allows us to share images. One can share pre-built images on the registry, while others can consume it with just one command. This is of great help for anyone using Docker, especially developers.

Q So Docker started a revolution in the world of containers. How can it be a vital tool for developers?

Docker is a boon to developers. It helps them to quickly prototype ideas. Using Docker Registry, developers
