

```
<body>
<?php echo "Project 1!";?>
</body>
</html>
```

Now, the result will be: Project 1!

What are PHP namespaces?

A namespace can simply be defined along with the namespace keyword and a name. Also, it needs to be declared prior to any other code along with the exemption of infrequently used declare statements. Thus, once a namespace has been defined, its scope applies to the whole file.

For example:

```
<?php
Namespace Mynamespace;
//....
```

It may also be defined alternatively just by covering its contents with brackets. Also, there is no code allowed outside the brackets apart from the formerly mentioned declare statement.

For example:

```
<?php
Namespace Mynamespace {
//....
}
```

The two methods discussed above cannot be combined, so the user should stick to any one of these methods, at a particular time.

Now let's get to know something about nested namespaces as well. These are defined by adding a backslash to separate each level.

For example:

```
<?php
Namespace Myassignment\blog\admin;
```

Nested namespaces can be easily defined in this way. Likewise, there are many other forms for namespaces like defining multiple namespaces, global namespaces, and a lot more.

Global namespaces

Global namespaces are great for simplifying storage organisation in environments that have abundant material file systems. These give a consolidated outlook into numerous network file systems, common Internet file systems, network-attached storage systems or file servers located in different physical locations. They are mainly helpful in dispersed implementations along with formless data. They also

support environments that are rising rapidly, so that data can be easily accessed without the need to know where it physically resides. Users should keep in mind that without a global namespace, multiple file systems would require to be handled individually.

Sub-namespaces

Namespaces can pursue a definite chain of command, like the directories in the file system on your desktop. Sub-namespaces are tremendously helpful for maintaining the arrangement of a project. For example, if your project needs database entrée, then you may need to put all the database-related secret code, like a database exemption and link manager, in a sub-namespace known as a database. Also, to uphold the suppleness, it is prudent to save sub-namespaces in sub-directories. This will allow you to structure your plan and will make it much easier to employ autoloaders that satisfy the PSR-0 criterion.

Calling code from a namespace

If the user needs to instantiate a new objective, then you need to either call a function or use a constant from a diverse namespace, along with using the backslash notation. This can be determined from the three dissimilar categories listed here.
