

Meta's Manus AI allows users to operate its agents through Telegram

The rise of OpenClaw is reshaping the AI agent market, compelling closed platforms to mirror features first popularised in the open source community. The latest example: Manus AI has introduced Telegram-based mobile control, a capability long central to OpenClaw's messaging-first approach.

The update allows users to operate 'Manus Agents' through Telegram, issuing chat commands to run research, manage inboxes, automate workflows, build apps and spawn sub-agents. The move signals how open source experimentation is increasingly guiding commercial roadmaps.

The contrast between the two remains sharp. OpenClaw runs locally, is open source and free, and offers greater privacy and user control. Manus AI is cloud-based, closed and subscription-led, requiring customers to trust Meta Platforms with their data.

Pricing widens the gap. Manus plans start at \$40 per month for 8,000 credits and scale to \$200 for 40,000, with credits draining quickly during heavy tasks. OpenClaw carries no licence cost, with users supplying their own compute.

Both platforms can deploy agents, automate tasks, organise email, browse the web and generate apps from prompts. Yet OpenClaw supports multiple social channels, while Manus currently offers only Telegram.

Meta acquired Manus in December 2025 and plans deeper integrations across Facebook, Instagram and WhatsApp.

Microsoft flags fake Next.js repos are embedding staged backdoors inside build scripts

Attackers are seeding the open source ecosystem with malicious yet legitimate-looking Next.js repositories that embed staged backdoors inside build scripts and

dependencies, according to Microsoft. Once cloned, routine commands such as `npm install` or `npm run build` quietly trigger command-and-control connections.

The campaign targets software developers who regularly clone public repositories to test coding challenges, assess recruitment

tasks or collaborate on open source tools. By exploiting default trust in shared code, the attackers turn standard development behaviour into the infection vector.

The technique abuses trusted workflows in Visual Studio Code and Node.js, hiding malicious logic inside package.json scripts, dependency chains and build processes rather than using conventional malware installers. Repositories are crafted to pass casual checks, complete with realistic commit histories, documentation and comments. Payloads are often obfuscated within ordinary JavaScript modules.

Impact extends beyond a single machine. Stolen credentials, session tokens and SSH keys can provide access to private repositories, corporate networks and cloud infrastructure, enabling lateral movement across organisations.

Microsoft said the activity reflects a broader shift towards supply-chain style intrusions that treat developers as privileged entry points. The framework itself is not vulnerable; instead, attackers manipulate normal workflows and trust in open source collaboration.

Developers are advised to verify repository sources and recruiter identities, inspect package.json and install scripts, run unfamiliar code inside virtual machines or containers, enable multi-factor authentication, and rotate credentials regularly. The episode underscores a widening trust gap in open source software consumption and the need for stricter code provenance and dependency checks.

DeepSig becomes a founding member of the Linux Foundation's OCUDU initiative

DeepSig has joined the OCUDU Ecosystem Foundation as a founding member, backing a vendor-neutral, open source framework under Linux Foundation

governance to standardise interoperable Centralised Unit and Distributed Unit software for Open RAN.

OCUDU establishes an open reference platform, integration tooling and continuous validation environments designed to cut

fragmentation and enable production-grade deployments across 5G and early 6G networks. The aim is to make open source the default foundation for next-generation RAN infrastructure rather than a research effort.

The stack builds on the Software Radio Systems 5G CU/DU solution, previously selected by the US FutureG Office with the National Spectrum Consortium, and has now transitioned into a fully open source project hosted by Linux Foundation. A three-year funded programme supports a DeepSig-SRS partnership to expand capabilities spanning advanced 5G features, early 6G, AI-native RAN and accelerated compute. An initial release is already live.
