

established open cloud-native philosophy into AI-led operations, strengthening SUSE's open source infrastructure position.

Liz now coordinates agents across fleet management, security, observability, cluster provisioning, and application lifecycle management, helping reduce operator cognitive load by automating diagnostics, CVE checks, remediation suggestions, and Kubernetes troubleshooting. Importantly, human approval remains the default for all create or modify actions, preserving enterprise-safe control.

“Our open approach to AI and the unification of VM and container management allows customers to capitalise on the potential of AI and redefine their own operational simplicity, ultimately giving them flexibility, choice and control,” said Peter Smails, general manager, Cloud Native, SUSE.

SUSE also strengthened its broader open infrastructure stack with updates to SUSE Virtualization, built on the open source Harvester HCI project. New additions include NVIDIA MIG support, VM Auto Balance, Live Storage Migration, and granular upgrade controls, enabling unified management of containers, virtual machines, and GPU workloads.

Chinese open source satellite AI allegedly helped Iran target US bases

US intelligence has alleged that Chinese AI company MizarVision published AI-enhanced satellite imagery of US military bases in the Middle East, complete with tagging metadata for aircraft, radar, ships, air defence systems, and base layouts.

According to the Pentagon's assessment, the Islamic Revolutionary Guard Corps (IRGC) used the publicly accessible data for missile and drone target prioritisation, turning commercial OSINT into operational strike intelligence and potentially endangering US and allied troops, including Australian personnel in the region.

The company's own stated mission sharpens the open source angle: “We believe that the power of open source can democratize and universalize geospatial intelligence.” That democratisation now appears to extend to military-grade AI tagging capabilities once reserved for national intelligence agencies.

The assessment gained urgency after MizarVision repeatedly posted imagery of Saudi Arabia's Prince Sultan Air Base in the week before the conflict. On February 24, Patriot air defence positions were identified; on February 27, dozens of aircraft locations were tagged. Less than 48 hours later, the base was struck, with US intelligence saying the specifically identified capabilities later became targets.

The AI platform can reportedly classify aircraft types, navy ships, radar systems, drone carriers, air defence deployments, and vessel routes across vast areas. Analysts warn this reflects a major capability shift, where state-grade intelligence workflows are now accessible through commercial open source AI tooling.

Meta's React Native 0.85 comes with enhanced animation performance

Meta has released React Native 0.85, advancing the open source cross-platform UI framework by pulling more ecosystem innovation directly into its core. The standout addition is the experimental Shared Animation Backend in version 0.85.1, developed in collaboration with Software Mansion, the team behind Reanimated.

The update moves key Reanimated logic into the React Native core, reducing overlap between Reanimated and the built-in Animated library. By shifting animation processing closer to the native layer, the release delivers better animation efficiency and performance uplift. Layout properties can now be animated in Animated through the Native Driver, a long-requested capability for developers building smoother native experiences.

The release also reflects a stronger open source modularisation strategy. React Native has removed the Jest preset from the main react-native package and moved it into the standalone @react-native/jest-preset package, reducing the framework core's footprint and making dependency management cleaner.

Further improvements include DevTools upgrades, such as support for multiple simultaneous CDP connections, while macOS users gain native tabs support.

On the compatibility front, React Native now drops end-of-life Node.js versions and releases below 20.19.4, while support for version 0.82 officially ends.

With React now under the Linux Foundation-backed React Foundation, the release underscores how open source collaboration is shaping the framework's core evolution.
