

integrations such as Azure Content Safety. The platform extends into FinOps with token-aware analytics, spend capping, and natural language insights, and enables monetisation through prepaid, pay-as-you-go, and outcome-based models via Moesif.

“Enterprises are now exposing APIs and proprietary data to AI agents, and that fundamentally changes the risk profile. Today’s gateways are blind proxies: they approve the 500th retry of a runaway agent the same way they approved the first. These new capabilities give organisations a way to stay in control as that shift accelerates,” said Derric Gilling, vice president and general manager of API Platform, WSO2. He added, “This is our first step in helping our customers become truly agentic enterprises.”

Plugin hijack raises an alarm across WordPress ecosystem

Dozens of plugins used within WordPress have been taken offline after a malicious backdoor was discovered, enabling attackers to inject harmful code into websites relying on these tools. The affected plugins, with over 400,000 installs, 15,000 customers, and presence across 20,000 active sites, point to large-scale exposure across the global web ecosystem.

The incident has been identified as a software supply-chain attack, where malicious code was introduced following a change in ownership. The backdoor remained dormant before activating in early April 2026, distributing malicious payloads at scale.

Austin Ginder, founder of Anchor Hosting, raised the alarm, and described a supply-chain attack on a WordPress plugin maker called Essential Plugin.

Plugins inherently require deep access to site infrastructure, making them high-risk if compromised. However, no user notification mechanism exists for ownership changes, exposing a major blind spot in open source ecosystems.

The plugin portfolio, originally developed by Minesh Shah, Anoop Ranawat, and Pratik Jain under WP Online Support, was rebranded as Essential Plugin and later sold in 2024 after a 25–30% revenue decline. The buyer, identified as ‘Kris’,

Chinese researchers cut bamboo drone control latency with open source flight controller

A research team from Northwestern Polytechnical University’s School of Civil Aviation in China has released what it describes as the world’s first open source flight control system for bamboo-frame drones, making the software freely available to accelerate the development of low-cost, eco-friendly UAVs.

The release addresses a long-standing bottleneck in bamboo drone engineering: combining bamboo’s non-traditional structural behaviour with high-performance autonomous flight control. Unlike composite airframes, bamboo structures generate low-frequency vibrations in the 8-20Hz range, a condition conventional flight controllers struggle to stabilise.

According to the team’s paper published in *Heilongjiang Science*, “Existing commercial flight controllers are either closed source and inflexible, or open source but poorly adapted to local development needs, limiting the industrialisation of bamboo-based UAVs.”

To overcome this, the researchers developed a custom flight control board built around an industrial chip and supported by a dual-inertial measurement unit (IMU) architecture. The team also redesigned the control algorithms specifically for bamboo’s structural dynamics, using a tuned extended Kalman filter and leveraging bamboo’s natural vibration-damping characteristics.

The optimisation reduced control latency from 15-20ms to 8-10ms, significantly improving responsiveness while maintaining flight stability. By removing reliance on rigid closed source controllers and introducing a purpose-built open platform, the project positions open source as a practical enabler for the industrialisation of sustainable bamboo-based UAVs.
