

India hits 27M on GitHub

With more than 27 million developers on GitHub, India is the world's fastest-growing developer hub and is reinforcing its leadership in global open source innovation.

The milestone is significant beyond scale. India is now the world's largest open source contributor base and the second-largest overall source of open source contributions, behind only the United States. Its growing influence is especially visible in AI, where Indian developers have made more than 7.5 million contributions to open source AI projects, making the country the second-largest contributor globally in this segment.

GitHub said more than two million developers joined from India in 2026 alone, accounting for one in seven new developers globally, the highest share from any country. "More than two million developers have joined GitHub from India so far in 2026, accounting for one in seven new developers globally — more than any other country. India is the world's fastest-growing developer community, and it shows no signs of slowing," the platform noted.

The momentum also reflects a strategic shift from contribution-led growth to product creation-led leadership. Indian-origin open source technologies such as Hyperswitch, ERPNext, ToolJet, and Bruno now see global adoption, strengthening the "built in India, adopted globally" narrative.

Kyle Daigle, chief operating officer, GitHub, said, "Behind India's economic growth is a relentless community of devs."

Claude Mythos triggers India cybersecurity review

Anthropic's unreleased AI model, Claude Mythos, is driving a new phase of AI-led open source security hardening, prompting the Indian government and the broader IT sector to reassess cyber risk exposure. Under Project Glasswing, a \$100 million initiative involving 40 companies and open source developers, Mythos is scanning global open source codebases to uncover hidden vulnerabilities before public release.

The model has already identified flaws in critical open source systems, including OpenBSD, FFmpeg, and the Linux kernel, with patches now being prepared ahead of wider disclosure. This early-fix approach is pushing MeitY officials and CERT-In to closely study the cybersecurity implications of AI systems that can both detect and potentially exploit software weaknesses.

India's open source AI boom outpaces patents, says Stanford

India's AI rise is increasingly being written in open source, with the country now accounting for 5.2% of all open source AI projects on GitHub with at least 10 stars, according to the Stanford AI Index 2026. More significantly, Stanford notes India's contribution trajectory is still climbing, even as China's comparable growth has slowed since 2019.

The data positions India's open source momentum as the strongest proof yet of its developer-led AI expansion, spanning collaborative tooling, model wrappers, libraries, agent frameworks, and public experimentation.

That ecosystem strength is reinforced by India's ranking #1 globally in relative AI skill penetration, with AI skills appearing on LinkedIn profiles at three times the global average.

Enterprise adoption is adding further fuel. More than 80% of Indian employees report using AI regularly at work, while 85–90% say their organisations actively support AI strategy and literacy, creating a strong feedback loop between workplace use and open tooling contributions.

Yet the Stanford report also highlights a structural contradiction: India's AI patent share remains just 0.4%, despite its fast-growing open source and talent footprint. The country has also recorded the sharpest rise in AI nervousness globally, up 14% year-on-year, suggesting that familiarity with AI is increasing awareness of its risks at the same pace.
