

Consensus Algorithms in Open Source Blockchains: An Overview

A blockchain is a decentralised digital ledger technology that allows for secure and transparent record-keeping of transactions within a distributed network. Each block contains the data for the transactions occurring during a specific period, and because each block is securely linked to the previous block, both data integrity and immutability are preserved.

Trust, transparency, and security have made blockchain a fundamental technology in a range of industries including finance, healthcare, supply chain management, and digital identity systems.

Role of consensus in blockchain

In a distributed blockchain setting, there must be agreement among many nodes so that the ledger is kept up-to-date and consistent. Consensus protocols specify how transactions must be validated before they can be added to the blockchain as part of a new block.
