

ESDS appoints new CEO

G.S. Murthy has joined ESDS as the new CEO, global business. He comes with 19 years of work experience in the technology sector.

Elaborating on the development, founder and MD of ESDS, Piyush Somani, said, "Many of us at ESDS have seen his leadership skills as well as his expertise

in technology from his Oracle days. We have experienced phenomenal growth in our business due to the growth in India's cloud market and now we are looking to expand offshore as well. Murthy, with his experience of working with large MNC IT giants, will help ESDS go to the next level."

Excited to join ESDS, Murthy said, "ESDS has the agility that most players in the market don't have today. ESDS' leadership skills, customer focus, relationship with the customers and technological expertise are its unique propositions. The company today is addressing real-time customer problems with its technical strengths. I'm sure we will win by creating competitive advantage for our partners and customers worldwide, by embarking on their digital transformation journey."

Talking about his role as the new CEO, Murthy said he would combine the strengths of ESDS with the MSP knowledge he brings. "I am looking at multiple geographies where we should be investing our time and money," he said.

Today, the cloud can actually take businesses to the next level and give them the ROIs. Without the cloud none of the new IT platforms like IoT, AI, FinTech, containerisation, mobility and others would have come into play. "Vertical auto-scaling is our biggest differentiator when it comes to IT cost control mechanisms, which is eventually going to make businesses succeed. Thus, I think it is time now for ESDS to move to the next level – and go global," he added.

Murthy has worked for top international IT companies like Oracle, IBM and HPE. In his last role as the chief technologist and global head – solutions and technology (Global System Integrators) at Hewlett Packard Enterprise, Murthy led the pre-sales and consulting alliance executive teams for GSI-I6 business, globally.

Open sourced hypervisor project to enable IoT device development

Yet another interesting hypervisor project has been announced by The Linux

Foundation. The project will provide a framework for industry leaders to build an open source embedded hypervisor specifically for the Internet of Things (IoT).

This new embedded reference hypervisor project is called ACRN (pronounced 'acorn'). With engineering and code contributions from Intel Corporation, the hypervisor was built with real-time and safety-criticality in mind, and optimised to

streamline embedded development.

ACRN comprises two main components: the hypervisor and its device model—complete with rich I/O mediators. Intel's experience and leadership in virtualisation technology were key to the initial development of this hypervisor solution.

ACRN's small, real-time footprint will help developers. Consolidating a diverse set of IoT workloads with mixed-criticality on to a single platform

GitHub's 'Licensed' will make open source project licensing easier

Open source licensing is complicated. Today, programs are 20 per cent original code on top of 80 per cent previously open-sourced code. To reduce the licensing complexities, GitHub has open sourced Licensed.

Licensed is a tool from GitHub, used to automate the licensing of some of GitHub's open source projects. It will help developers efficiently use their code's open source licensing by spotting potential problems with a program's dependency licence early in its development cycle.

Licensed works in any Git repository, by finding, caching and checking licence metadata for dependencies. It can detect dependencies from multiple language types and package managers across innumerable projects in a single repository. This flexibility allows it to work equally well for a repository holding thousands of projects as it would for a repository containing a single project.

This new open source program operates on the concepts of 'applications'. An application is defined as the combination of a source location and a cache directory. A configuration file is used to specify one or more applications that you're checking for licensing concerns.
