

C++ compiler open sourced to speed up compile time

To speed up compile times while being a drop-in replacement to GCC (GNU Compiler Collection) or Clang, the Zapcc C++ compiler has been open sourced.

According to Zapcc, the compiler offers improvements in both incremental and full builds compared to building with Clang 4.0 and Clang 5.0, which are based on heavily modified code from the Clang compiler project.

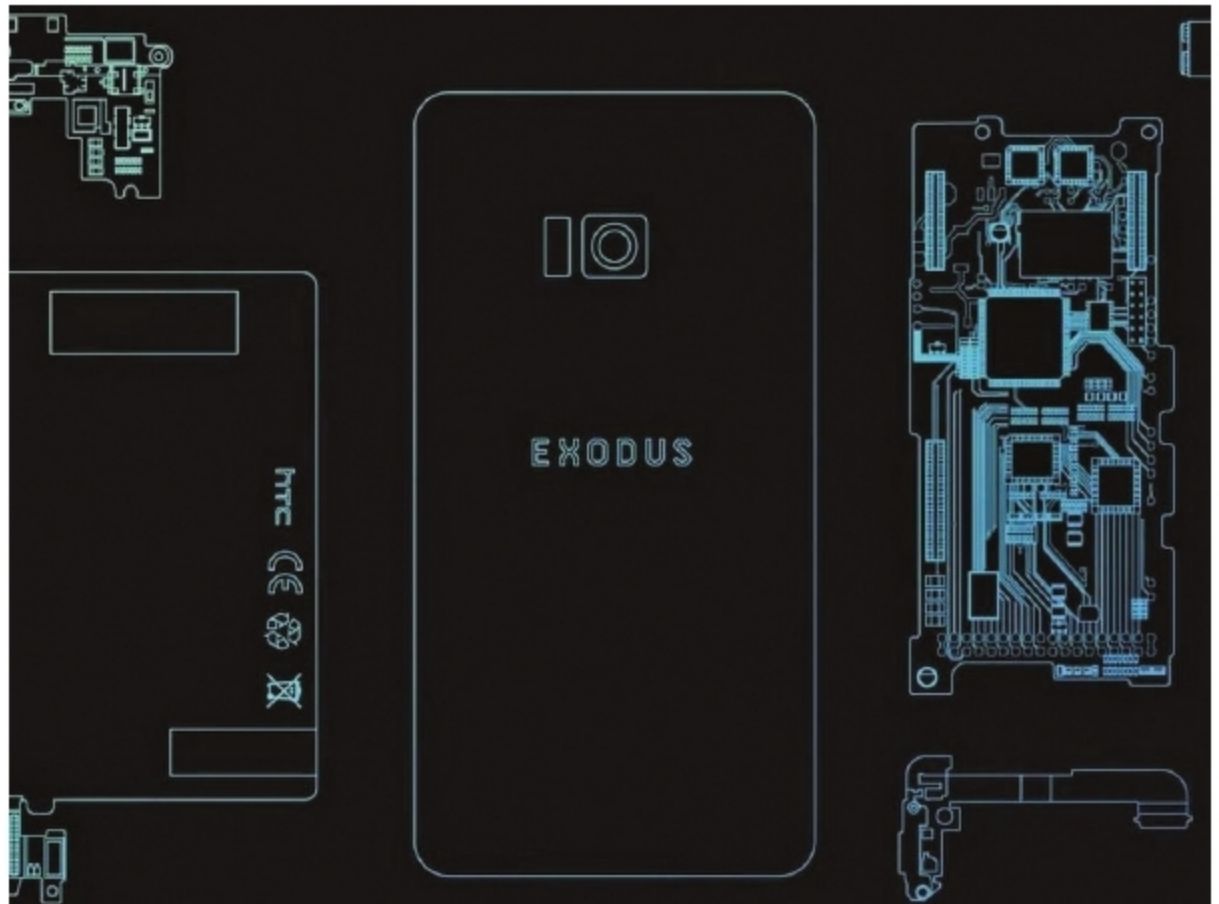

The compiler makes practical use of an in-memory compilation cache in a client-server architecture where all the compilation information is recalled between runs.

Its applications are in an existing build and avoid precompiled headers, an approach that requires a project to be built to specific header rules. Precompiled headers also do not cache to the same extent as Zapcc. C++ modules are not standard, are hardly used and do not support legacy code or C++ macros well.

C++ modules also require refactoring or they are slow. CC is a caching C++ compiler based on a fork of Clang/LLVM that its developers claim is up to 50 times faster on recompilations and two to five times faster on full builds.

The core idea behind the Zapcc compilation speedup is to use a compilation server, which stays in memory and receives compiled commands from the clients. Zapcc parses C++ header files just once and keeps in memory all template instantiations and generated code.

It is compatible with the GNU Compiler Collection (GCC) to the extent that Clang is GCC-compatible. The command syntax is similar to Clang as well, with the command being *zapcc*. It supports only Linux x64; experimental support is offered for Windows x64.

year, as Bitcoin prices were rising rapidly, the idea appeared more attractive and quickly grew into a strategy.

Recently, the cryptocurrency mania has died down as the frequency of scams and hacks has become a cautionary tale. There are claims that phones with a cryptocurrency wallet can be a secure hardware wallet. HTC also hopes that trading virtual cats (because of the CryptoKitties game) will encourage gamers and people who are less familiar with cryptocurrency to try out the Exodus. Gaming is the most approachable way for the non-crypto crowd to try their hand at mining on the mobile, a source at HTC said.

Blockchain doesn't make sense to a lot of people. With the Exodus, HTC is hoping that they will get people to become individual nodes, as each Exodus device will form one node in the blockchain. But the problem is, does anyone want to be in that chain?

Container image builder for Java applications

In order to enable developers to build Java containers with familiar tools, Google has launched Jib, an open source Java tool. It has been talked of as a container image builder that can handle the process of packaging a Java application into a container.

Container technology aims at providing application developers a way to build, deploy and run applications irrespective of the underlying infrastructure.

The just launched tool has been designed to simplify containerising a Java application.

Developers say that Jib is integrated with the Maven and Gradle Java development environment. They also claim that the tool eliminates the need to maintain a Dockerfile and create a Java Archive.
