

Blockchain platform to allow interoperability and privacy

R3 has launched a commercial version of its open source blockchain platform, Corda, to provide privacy and security solutions.

The launch of Corda Enterprise by R3 means companies can now select a version of Corda that addresses their needs irrespective of the industry, size and stage of development. This can let a wider range of institutions realise the potential of blockchain technology.

The commercial version includes a blockchain application firewall that can

enable the platform to be deployed in corporate data centres while retaining the

ability to communicate securely with other nodes anywhere else in the world.

This can unlock opportunities for R3's partner firms to expand their business and serve a growing community of end users in sectors as diverse as insurance, healthcare, shipping and financial services.

Interoperability has been suggested as a key aspect of the platform's design. Its applications and services run across a common layer of identity, consensus and governance. This means businesses can transact with all their business partners without trapped assets or islands of information.

Corda and Corda Enterprise are interoperable, which means that companies using either can trade with each other, and that one organisation can run both platforms across different divisions.

The version comes with additional features including optimisation for real-world corporate IT environments. It supports Oracle and SQL server databases, and comes with cross-distribution and cross-version wire compatibility.

Nutanix Velocity programme for hyper-converged software product

The Nutanix Velocity programme involves selling processes, incentives and marketing investments. It is directed towards key partners focused on the mid-market segment. As a part of the programme, Nutanix has partnered with Lenovo, which will provide HX product bundles for mid-market customers.

A hyper-converged software-ready product offering called Lenovo ThinkAgile HX Certified Nodes will be launched by the two companies, specifically for enterprise customers. This will allow Nutanix's partners to build their own deployment and professional services opportunities to increase customer value on the built solutions.

The programme also aims at providing the company's partners with incentives and opportunities to provide the Nutanix Enterprise Cloud OS software to customers in the mid-market segment. It is an attempt to demonstrate how hyper-converged infrastructure can be a solution to security challenges in public cloud-only models.

The product bundles consist of a purchasing path for pre-defined bundles and various configurations. The company's partners can use these offerings to grow their business through streamlined sizing and quoting.

The programme can provide enterprises with choices of software licensing terms and conditions that are suitable for their business needs. It will also enable customers to purchase the company's software licence separately from the ThinkAgile platform and gain access to software support from its customer services organisations.

With this, the company is planning to provide rewards and incentives to partners who invest in its business. This partnership can also help develop hyper-converged infrastructure and provide offerings for enterprise IT customers.

Commvault-IBM partnership to enhance data management and protection

Commvault's partnership with IBM may enable IBM Business Resiliency Services to provide its global customer base with a single powerful platform for managing,
