

Master Password App: A Safe and Random Password Generator

Passwords and PINs are the bane of modern day living. Passwords are sometimes forgotten and often they are hacked with disastrous consequences for the user. The Master Password app simplifies things. The user has to only remember one master password. Then site-specific random passwords are generated which the user does not have to remember. This makes for better security.

Passwords are ubiquitous. Most of the sites you visit on the Internet enforce the use of passwords in one way or the other. An average user has 25 online accounts that are password protected. Since password usage has increased dramatically, it has also created serious problems from the security point of view.

When the number of passwords increases, the quality and strength of the password get diluted. For a majority of users, keeping track of the passwords is a headache, so they end up using weak passwords or, even worse, they use the same password for all their online accounts.

These issues can be overcome with the Master Password app— a stateless password generator that creates strong and random passwords.

What is the problem?

The number of online accounts we use is doubling every five years but the security measures around these online accounts

are getting flimsier. We can see that new vulnerabilities are being discovered every day, passwords are getting leaked and other security breaches are taking place, suggesting that we need to fortify our online accounts. This may seem a lot of work but it has also become necessary.

The following general practices related to passwords make using the password system almost pointless.

Using the same password: The use of the same password for various accounts is increasing. A survey estimates that 80 per cent of people use the same passwords for many accounts. They mainly do this because every time they have to create an online account, they also have to create a new password, which is a lot of work. Even when they set up a new password for every online account, there's the risk of the user forgetting it. To avoid this, the same password is used for all the accounts. If a hacker gets hold of your password on any one of the accounts, then all other accounts are also compromised.
