

Top Ten Open Source Tools for Building Websites

You can build a website to grow your business using these popular free and open source website building tools.

Nowadays, whether you are an individual entrepreneur or representing a business organisation, a website is a must for personal and professional growth. Organisations are spending lots of money to build attractive websites. In this article, we are going to look at some of the open source website building tools that you can use to build your website on your own, without much knowledge about programming or the Internet.

1. WordPress

WordPress is one of the most popular open source free CMS (content management system) frameworks available in the website market. The majority of those who don't know much coding prefer to create a website using WordPress. There are two variants of WordPress. The first is *wordpress.com*, where you can host your own website, which will have a domain name *wordpress.com* at the end – for example, *maulikparekh.wordpress.com*.

By paying an amount, you can change the name to your own domain name, say, *maulikparekh.com*.

The second variant is *wordpress.org*, where you can download the WordPress framework and install it on your own host providers. Most host providers, by default, support WordPress so we don't need to install it. But we need to buy everything, like the domain name and hosting space. Based on their requirements and experiences, people choose different options.

If you are a fresher, then you can start with *wordpress.com* and later, once you are comfortable, you can migrate to *wordpress.org*. If you don't have money constraints, then I will definitely advise you to go with your own hosting website using *wordpress.org* because you can get more freedom, speed, performance and flexibility, all of which are not optimal in *wordpress.com*. The WordPress framework is written in PHP.

The official websites for WordPress are <https://wordpress.com> and <https://wordpress.org/>.
