

Red Hat OpenShift Container Platform 3.7 released

Red Hat has launched the latest OpenShift Container Platform 3.7, the version of Red Hat's enterprise-grade Kubernetes container application platform. As application complexity and cloud incompatibility increase, Red Hat OpenShift Container Platform 3.7 will help IT organisations to build and manage applications that use services from the data centre to the public cloud.

The latest version of the industry's most comprehensive enterprise Kubernetes platform includes native integrations with Amazon Web Services (AWS) service brokers, which enable developers to bind services across AWS and on-premise resources to create modern applications while providing a consistent, open standards-based foundation to drive business evolution.

"We are excited about our collaboration with Red Hat and the general availability of the first AWS service brokers in Red Hat OpenShift. The ability to seamlessly configure and deploy a range of AWS services from within OpenShift will allow our customers to benefit from AWS's rapid pace of innovation, both on-premises and in the cloud," said Matt Yanchyshyn, director, partner solution architecture, Amazon Web Services, Inc.

Red Hat OpenShift Container Platform 3.7 will ship with the OpenShift template broker, which turns any OpenShift template into a discoverable service for application developers using OpenShift.

OpenShift templates are lists of OpenShift objects that can be implemented within specific parameters, making it easier for IT organisations to deploy reusable, composite applications comprising microservices.

Building secure container infrastructure with Kata Containers

The OpenStack Foundation has announced a new open source project—Kata Containers, which aims to unite the security advantages of virtual machines (VMs) with the speed and manageability of container technologies. The project is designed to be hardware agnostic and compatible with Open

Container Initiative (OCI) specifications, as well as the container runtime interface (CRI) for Kubernetes.

Intel is contributing its open source Intel Clear Containers project and Hyper is contributing its runV technology to initiate the project. Besides Intel and Hyper, 99cloud,

AWcloud, Canonical, China Mobile, City Network, CoreOS, Dell/EMC, EasyStack, Fiberhome, Google, Huawei, JD.com, Mirantis, NetApp, Red Hat, SUSE, Tencent, Ucloud, UnitedStack, and ZTE are also supporting the project's launch.

The Kata Containers project will initially comprise six components, which include the agent, runtime, proxy, Shim, kernel and packaging of QEMU 2.9. It is designed to be architecture agnostic and to run on multiple hypervisors. Kata Containers offers the ability to run container management tools directly on bare metal.

"The Kata Containers Project is an exciting addition to the OpenStack Foundation family of projects. Lighter, faster, more secure VM technology fits perfectly into the OpenStack Foundation family and aligns well with Canonical's data centre efficiency initiatives. Like Clear Containers and Hypersh previously, Kata Container users will find their hypervisor and guests well supported on Ubuntu," said Dustin Kirkland, vice president, product, Canonical.

Fedora 27 released

The Fedora Project, a Red Hat sponsored and community-driven open source collaboration, has announced the general availability of Fedora 27. All

editions of Fedora 27 are built from a common set of base packages and, as with all new Fedora releases, these packages have seen numerous tweaks, incremental improvements and new additions. For Fedora 27, this includes the

GNU C Library 2.26 and RPM 4.14.

"Building and supporting the next generation of applications remains a critical focus for the Fedora community, showcased in Fedora 27 by our continued support and refinement of system containers and containerised services like Kubernetes and Flannel. More traditional developers and end users will be pleased
