

A Quick Look at Cloonix, the Network Simulator

Cloonix is a Linux router and host simulation platform. It fully encapsulates applications, hosts and the network. Simulators like Cloonix offer students and researchers scope for research into various Internet technologies like the Domain Name System (DNS).

Cloonix is a network simulator based on KVM or UML. It is basically a Linux router and host simulation platform. You can simulate a network with multiple reconfigurable VMs in a single PC. The VMs may be different Linux distributions. You can also monitor the network's activities through Wireshark. Cloonix can be installed on Arch, CentOS, Debian, Fedora, OpenSUSE and their derivative distros.

The main features of Cloonix are:

- GUI based NS tool
- KVM based VM
- VMs and clients are Linux based
- Spice server is front-end for VMs
- Network activity monitoring by Wireshark

The system requirements are:

- 32/64-bit Linux OS (tested on Ubuntu 16.04 64-bit)
- Wireshark
- Cloonix package: http://cloonix.fr/source_stored/cloonix-37-01.tar.gz
- VM images: http://cloonix.fr/bulk_stored/

To set it up, download the Cloonix package and extract it. I am assuming that Cloonix is extracted in the *\$HOME* directory.

The directory structure of Cloonix is as follows:

```

cloonix
