

Note 2: Since there is no Active Directory server running in the classroom, there is no current possibility to practice these steps.

The following is an example of using `realmd` to join an Active Directory domain, and allow Active Directory users to log into the local system. This example assumes that the Active Directory domain is called `domain.example.com`.

- Install `realmd` as follows:

```
# yum -y install realmd
```

- Discover the settings for the `domain.example.com` domain by using the following command:

```
# sudo realm discover domain.example.com
```

- Join the Active Directory domain — this will install all necessary packages, and configure `sssd`, `pam`, `/etc/nsswitch.conf`, etc.

```
# sudo realm join domain.example.com
```

The above command will attempt to join the local system to Active Directory using the administrator account. So enter the password for this account when prompted. To use a different account, use the `-user` argument.

- The Active Directory account is now usable on the local system, but logins using Active Directory are still disabled. To enable logins, use the following command:

```
# sudo realm permit --realm domain.example.com --all
```

To only allow certain users to log in, replace `--all` with a list of those users. For example:

```
# sudo realm permit --realm domain.example.com DOMAIN\NAME1  
DOMAIN\NAME2.
```

Note : By default, domain users must use their fully qualified names to log in -- e.g., `user@ipa.example.com` for IPA users, or `DOMAIN\Picard` for Active Directory. To disable this, change the `use_fully_qualified_names` settings in the correct domain block in `/etc/sss/sss.conf` to `False`, or remove these entirely and then restart the `sss` service.
