

New library to secure AI systems

IBM has released a security library into the open source community that is designed to help protect artificial intelligence (AI) systems. IBM's aim is to make this toolbox become a repository and source of information on threats to current and future AI solutions.

Certain weaknesses in AI systems expose them to exploitation, such as undetectable alterations in content

including images, video, and audio recordings being crafted by those with malicious

intent, for which one does not need a deep knowledge of AI.

These changes can be small in size but result in huge security breaches. They impact the performance of AI systems like prompting them to make a choice which would be deemed malicious.

Aimed to combat so called 'Adversarial AI', the toolbox records threat data as well as assists developers in creating, benchmarking and deploying practical defence systems for real-world AI. IBM shared that this research looks at the best ways to defend the AI systems before the bad guys attack.

By introducing the toolkit to the open source community, others may also become inspired enough to create solutions before Adversarial AI becomes a true threat. The toolbox also includes a library, interfaces, and metrics that will help developers begin to create cyber security solutions for this emerging field.

"Considering tools didn't provide the defences needed to protect AI systems, this is the first and only AI library that contains attacks, defences, and benchmarks to implement improved security," the company sources have said.

The platform also helps software development and operations teams to streamline life cycle management of traditional and new cloud native applications. Unlike other Cloud Foundry offerings, SUSE Cloud Application Platform packages SUSE Cloud Foundry as a containerised distribution, managed by Kubernetes. By simplifying the deployment and management of SUSE Cloud Foundry, it makes the platform more accessible to existing Kubernetes users.

Abby Kearns, executive director, the Cloud Foundry Foundation, said, "SUSE continues to push our community to think and move in new and exciting directions. The recently certified SUSE Cloud Application Platform expands the Cloud Foundry ecosystem, creating more choices for enterprises."

Customers can use new backup/restore capabilities to simplify recovery of the SUSE Cloud Foundry environment, including applications. They can also use them to migrate from one Cloud Foundry instance to another, moving between private and public cloud instances, for example, or between different Cloud Foundry distributions.

Reliance to invest US\$ 180 billion in an open source education platform

Over the next three years, Reliance is going to invest up to US\$ 180 billion on an artificial intelligence (AI) based open source education platform called 'Embibe', a product of Indiavidual Learning Pvt Ltd. Reliance recently entered into an

agreement to acquire a major stake in this company.

On this platform, each student will receive personalised learning results with the help of data analytics on an AI based open source education platform.

Investments will be made in extensive R&D over the next three years in the education field using AI. 'Embibe' will

enable students from across the globe as well as in India access the open source curriculum and enhance their professional skills, higher education, local languages and everything related to curriculum categories.

The open source technology platform built by Reliance, will deliver customised learning that is highly scalable in nature across all education markets. The platform will use open source technology integrated with AI stacks concentrating on student intelligence, behavioural recommendations, content intelligence and automation.

The Israeli government chooses open source

After the US, the UK and France, the government of Israel has announced its shift to open source. The Israeli government will be making its software code available to members of the public.

Post the shift to open source, the public can use and modify the software, point out vulnerabilities and propose improvements. It will also be available for use in development apps.

Open sourcing the code will allow taxpayers to access the software and even use it in their personal projects. Moreover, it will enhance the security as researchers will be able to perform vulnerability checks with ease.
