

Setting Up Icinga 2, an Open Source Network Monitoring Solution, on Ubuntu 17.10

Icinga is an open source network monitoring tool for infrastructure of all sizes. It has an integrated cluster system secured via SSL. It keeps a watch over networks as well as other resources, notifies the user of errors and recoveries, and generates performance data for reporting.

In order to build up networks in small or large organisations, systems and network administrators start with the design and analyse process, before choosing the specific hardware that meets the requirements of the organisation. Many companies need their network to be up and functioning to generate revenue, so having the right set of tools to monitor, manage and administrate it is critical.

Today, various commercial, freeware and open source tools are available to choose from. So the debate continues about which tool to choose, and whether that tool has the features that meet the organisation's monitoring requirements. Network monitoring is a highly sensitive administrative task. It gives administrators a clear view of devices, services and applications running in the network, apart from the

opportunity to track the availability and performance of resources. This enables proactive management rather than reacting to issues after they happen.

There are various excellent open source network monitoring tools like Nagios, Zabbix, Libre NMS, Icinga 2 and Pandora FMS, but it is also possible to monitor networks manually. The latter option depends on the size of the network and how critical the resources on the network are. The safest choice is to deploy one of the best network monitoring solutions—Icinga 2, on Ubuntu 17.10.

Icinga 2

In 2009, a group of developers from the Nagios community announced a fork called Icinga because they were
