

them to production. Testnet offers developers a sandbox environment to experiment in without having to use real cryptocurrency or worrying about breaking the main chain. Both Ethereum and Bitcoin have different criteria for the blockchain Testnet.

To work on the Bitcoin Testnet, you must generate a differently formatted Testnet Bitcoin address which always begins with 'm' or 'n'. For Ethereum, the same address can work on both the Testnet and main net; hence, you need to be careful to not to mix them.

Among the two common ways to obtain Testnet coins easily, the first is by solving cryptographic puzzles. These Testnet chains have fewer miners and the level of difficulty is low, which makes it easier to find the solution for a hash puzzle to obtain a block reward. The other way to get these Testnet coins is by using faucets. These are the websites that dispense a small amount of Testnet coins in exchange for completing some task for their website.

Mist

Most people get confused as there are two terms related to Mist in Ethereum. The Mist-Ethereum wallet is the one that is most commonly used. The name, Mist, is also used for the browser. The Mist-Ethereum wallet allows you to store and send your ether. It is different from the Ethereum wallet, which is online. Whereas Mist runs from your computer and must be downloaded to be used.

The Mist browser is a special-purpose browser that offers an overall view of the Ethereum blockchain and all the tools that are needed to interact in blockchain components like ether,

DAO and smart contracts. However, it is still at the beta stage.

The Mist browser was introduced to build the third-generation Web (3.0), which envisages eradicating centralised servers and using Ethereum, Whisper and Swarm as their replacements.

Coinbase API

Coinbase API allows you to build new Bitcoin apps as well as integrate Bitcoin into already existing applications. The system provides a wide range of capabilities — from gathering read-only data to building something completely new. It also offers a system to create Bitcoin wallets and addresses, as well as to buy, sell, send and receive Bitcoins worldwide. It provides several client libraries and mobile software development kits (SDK) for developers. It allows developers to access and integrate the functionality of Coinbase with other applications.

Tierion

Tierion is used by developers to anchor data to the blockchain to prove the integrity and provide the timestamp of any data. It offers developer tools and APIs to add data to a distributed ledger. It also has an open standard called ChainPoint, which allows the user to record and generate receipts that contain all the information needed to verify data and avoids the need to rely on intermediaries. **END**
